So far I have sketched as briefly as I could the source from which the water is derived, the formation of reservoirs and primary rigoles, and their general disposition with regard to each other. I have omitted all minor details, as these would only serve to encumber the report. I will now try to describe how the water which has been led away by a primary rigole is distributed over the soil.

It is evident from Fig. I. that only those fields which lie below the primary rigoles are accessible to irrigation. When water flowing in a conduit traced horizontally on an inclined slope is suddenly arrested, it accumulates behind the stoppage, and eventually *déverse* itself, i.e., overflows the lower lip of the conduit. This is the sole principle of the hill-side system of irrigation. There is a good deal of diversity in the formation and tracing of the rigoles of *déversement*.

For lands of average inclination, of which the slope does not exceed 1 (1/10), a series of secondary rigoles—known as *rigoles of repartition*, at intervals of about 50 metres, originate in the primary rigole, and are directed straight down the side of the hill. The bottom of these derivatives is made about an inch higher than that of the primary rigole which can thus aliment several of them at a time. From the secondary rigoles of repartition, smaller rigoles of *déversement* branch out on both sides. The latter are traced almost perfectly horizontal; they are about 5 metres from each other. Fig. IV shows a portion of a meadow laid down in the way described above. Where the rigoles of repartition originate from the primary rigole, small *vannes* or sluices (V) are placed; the communication, however, between the former and the small rigoles of *déversement* is free, a small piece of plank, or stone or brick serving the purpose of a sluice at the time of irrigation. To begin with, the irrigator opens as many *vannes* (V) as the primary rigole can feed at the same time; he next arrests the downward flow of water by placing pieces of stone, etc., across the descending rigoles immediately below the first pairs of embranchments; the water is thus diverted into the latter, and soon begins to *déverse* itself by their inferior border. When the first strip has been thus watered, the irrigator replaces the stones at the second embranchments, which done, and the third ones, and so on, to the bottom of the meadow. It will be observed that any pair of the little rigoles of *déversement* serve as well as rigoles of evacuation for the pair immediately above it. When watering with a continuous current is desired as in winter, water being then very plentiful, the passages at the embranchments are half closed, so that the lower portion of the fields may still get some virgin water.

When the slope of a meadow exceeds $\frac{1}{10}$, the system indicated above is no longer applicable, as water would then flow with excessive rapidity in the descending rigoles, and thus it would be extremely difficult to divide it regularly in the horizontal rigoles of *déversement*. On such lands, the system of irrigation is very simple as will be seen in Fig. V. When water has to be carried over long distances (say) over 50 metres and more, the primary rigole is hardly used for *déversement*, as the flow of water is then too strong to allow of a uniform overflowing. In the latter case it gives rise to smaller rigoles which serve for *déversement*, as shown in Fig. V. For shorter distances, the primary rigole can serve as well for *déversement*. It is evident that with very broad meadows it would take a long time for the water to flow down the entire side; besides it thus flowing it would lose all its financial value before it would reach the lower level. Moreover, where the soil is very light and water is scarce, it is impossible to water the whole meadow by a single *déversement*. To avoid these difficulties parallel horizontal rigoles are traced at intervals depending on the slope and nature of the ground, (generally from 10 to 15 meters.) Each of these rigoles is fed either independently from the reservoir, or by the primary rigole at the top. They are quasi-horizontal, unless they serve as well to carry water to other parts, when a feeble slope is given to them.

On the school farm at Lézardeau there are two large reservoirs, and 4 or 5 smaller ones. Irrigation begins with October, and is continued all winter and spring within the second or third week before mowing. In winter the reservoirs are usually full and waterings follow each other as closely as possible. In spring they are given at intervals the period of watering gradually shortening as water gets scarce and grass becomes ripe for mowing. Irrigation is stopped during the entire mowing season; a few waterings are given in summer between the mowings and pasturing, but they are too limited then, as water fails in this season.

The superior effects of irrigation are eminently striking at Lézardeau, although the climate is very humid. The meadows afford two heavy mowings in the season and a subsequent autumn pasturage. Of the various beneficial results obtained on the farm it is none the less important to observe that irrigation has supplied one of the best means to get rid of *farus* and other noxious weeds, as these cannot stand long waterings and soon give way to useful plants which then push up vigorously.

MORE ABOUT BIJOO (SEEDLING) MANGOES.

[By Dr. E. BONAVIA.]

SOME time ago (9th July 1885) a native friend sent me some "bijoo am," (seedling mangoes). They were out and out the finest flavoured mangoes I had tasted that season. They were larger than the Bombay mango, of a pale yellow color inside, a little stringy, but the flavour was exquisite, a mixture of sweetness, with a little subacid, and just enough of that charming turpentine aroma, to remind one he was eating a delicious mango, and not a delicious anything else. The whole was a "bouquet" of flavours, which I don't remember having experienced since I have been in India. All this was enhanced by the lateness of this variety, all others having ceased long ago. Natives have a pull over us. They don't eat mangoes with a spoon, but suck them. We therefore exclude from our palate some of the most deliciously flavoured mangoes, simply because they happen to be a little stringy. This 'bijoo,' and others of its stamp, are varieties truly worthy of being propagated and multiplied by grafting. Cultivation might lessen its stringiness, but it could hardly improve its charming 'bouquet.' The unfortunate accident of some varieties being called 'bijoo' and others 'kalai,' (grafts) may have put a stamp of contempt on the former, and have led to their eventual loss by extinction for want of multiplying them by 'kalam.' Their caste name having stamped them with unworthiness of propagation by graft, while an inferior "kalai," mango may have been propagated and patted and cared for, simply because it was a 'kalai' one. It is much the same with the epithets 'Deseo' (country) and 'Bilateo' (English). The former means neglect, the latter attention, often irrespective of the quality of the tree. It is difficult to

convey any accurate idea of the combined flavour of the 'Bijoo' mango in question: one might perhaps convey some idea by saying it was like a mixture of pine-apple, custard-apple, nectarine and something else, with a finish *sui generis* mango flavour! The lesson to be learnt from this delicious 'Bijoo' mango, however, is that good *seedling* varieties of mangoes are as worthy of being propagated and multiplied by grafting, and of being manured, and cultivated, as any 'kalmi' mangoes, and in some cases, perhaps more so.

Miscellaneous Items.

We are told that Mr. Yasuda, of the Agricultural and Commercial Department, who is acting as Japanese Commissioner to the International Exhibition in London, has written to the Government that the Japanese display receives the highest praise, and is eagerly visited.

It is stated by the *Japan Mail* that an analysis to determine the percentage of nicotine in tobacco grown in various parts of Japan has been made at the Tokyo Laboratory, when it was found that none contained more than 3 per cent. Nicotine in foreign tobaccos is frequently as much as 7 per cent.

The *Japan Mail* says:—The oft-repeated assertion that in the Hokkaido lie the hidden resources of Japan is being gradually realized. The most recent discovery is an excellent clay which has been found in the neighbourhood of Mombetsu. An official examination has proved it to be as good and as fit for the manufacture of porcelain as that found at Imari.

We (*Singapore Free Press*) are informed that the Exhibition Commissioners have allotted 5,600 square feet in the Eastern Arcade and Gallery of the Colonial Exhibition to this Colony. The situation is not very favourable as it is some way from the main entrance, and rather out of the ordinary course of visitors. The Committee have decided on applying to the Commissioners to remove the Court, if possible, to a more central position. It is hoped that a good number of exhibits will be got together during this month. It is proposed, if possible, to hold a public exhibition of the exhibits before they are packed for transmission to London. We have had the pleasure to see some models that are being made by Mr. Pickering, C.M.G., comprising a street of Chinese shop-houses, with a number of natives of different kinds walking along the road. The shops are of a large size, and suit the figures, which are about six to eight inches high. It is a marvel of patience and ingenuity. Mr. Pickering has also made a number of models of native boats with sailors and fishermen in them. It will be a thousand pities if they are sent to London before people can see them here.

Two special committees have been appointed for the purpose of buying remounts, for the Bengal and Punjab Cavalry, at the horse fairs in Upper India this cold weather. The North-West Provinces and Oudh Committee is composed of the following officers:—Colonel R. M. Clifford, 9th Bengal Cavalry (President), and Major C. E. Salkeld, 2nd Bengal Cavalry, Major G. W. Deane, 13th Bengal Lancers (members); Veterinary Surgeon E. H. Kelly attached. The Punjab Committee consists of Colonel Seymour Barrow, President, and Major R. C. Hutchinson, Corps of Guides, and Captain P. R. Barnsfather, 14th Bengal Lancers (members); Veterinary Surgeon R. Pringle attached. No remounts are to be bought for the native cavalry at any horse fair, except by these two Committees. The horses they buy will be assigned to the various regiments wanting remounts, by drawing lots. It is ordered that remounts otherwise fit for service are not to be rejected on the ground of colour. The North-West Provinces Committee will buy for the 2nd, 4th, 5th, 7th, 8th, 9th, 11th, 13th, 16th and 19th Regiments of Bengal Cavalry. The Punjab Committee is to buy for the 1st, 3rd, 5th, 10th, 12th, 14th, 15th, 17th, and 18th Bengal Cavalry, the 1st, 2nd, 3rd and 5th Punjab Cavalry, and the Guides Cavalry.

The Department of Agriculture and Commerce, says the *Japan Mail*, has taken a step which may be regarded as supplementary to the inauguration of Tea Associations last year. Inspectors are to be sent to the tea and silk districts for the purpose of suggesting improvements in methods of cultivation and preparation, and urging greater precautions against adulteration. We judge from this that the Government deem it necessary to extend their paternal

role, for which judgment they will be roundly condemned by some foreign critic. It may be observed, however, that if official aid is to be rendered to agriculturists at all, it could scarcely assume a less objectionable form than that now proposed. Assuming that the inspectors chosen by the Government will be men well versed not only in the processes of sericulture and tea-production, but also in the conditions of the foreign trade in these staples, they will be in a position to give the people much useful advice, without resorting to any vexatious interference. One excellent task which they may set themselves to perform, is to preach everywhere the substitution of mulberry plantations for rice fields, and, indeed, the general abandonment of rice-growing throughout the land. Nothing is more essential than this if the Japanese race is to be maintained. There is no form of agriculture more degrading and unwholesome than the cultivation of rice, and there has never yet been a nation which rose to real eminence on a diet of rice.

Selections.

TRADE OF RUSSIAN TURKESTAN.

THE Russian official paper entitled the *Journal of the Finance Minister* has just published the following highly important and interesting article on the progress of the trade and industry of Turkestan. We print a translation of the whole of this contribution to our knowledge of Russian Central Asia:—

Since 1864 the administrative frontiers of Turkestan have undergone several changes. At the very first the jurisdiction of the Governor-General extended only over the districts of the Sir Daria and Semiretchinsk which together covered about 750,000 square versts, for the most part consisting of barren steppes. But before long several conquests gave Turkestan more fertile possessions. In 1868 there was added to the two districts named the province of Zerashan, a fertile valley through which passes the river of the same name. Between 1871 and 1873 Kuldja was next annexed in addition to that part of Khiva which lies on the right banks of the Amu Daria. Finally, in 1875-76 the territory of Ferghana, or the old khanate of Khokand, was joined to Turkestan, so that in 1877 Turkestan had an administrative jurisdiction of 1,032,500 square versts and a population of 3,150,000 persons. Still later on a separate government was formed in 1882 for the steppes, comprising the district of Semiretchia, and then the administration of the Governor-General of Turkestan was confined to the districts Sir Daria, Ferghana, Zerashan, and Amu Daria, or about 610,000 square versts, with a population of 2,335,000. This territory touches on the south and west the khanates of Khiva and Bokhara, and the Chinese possessions in Kashgaria on the east, while to the north it is bounded by the Governorship of Orenburg. The present territory of Turkestan may thus be divided:—

	Extent in Sq. Versts.	Settled Popula- tion.	Nomad Popula- tion.	Total Popula- tion.
Sir Daria	416,750	50,000	654,000	1,154,000
Ferghana	85,000	540,000	150,000	690,000
Zerashan	23,250	360,000	...	360,000
Amu Daria	86,000	30,000	101,000	131,000
Total	611,000	1,430,000	905,000	2,335,000

The atmospheric conditions and the character of the soil present striking contrasts throughout this vast region. A sandy soil very imperfectly watered by the Sir and Amu Darias rivers which have no affluents, and by the Aral Sea, stretches to the north. The steppes between the two rivers named are covered with thin herbage, without the smallest trace of a forest, and they are remarkable for their barrenness, and can only be utilized for pasturage by the nomads. In the south and east numerous branches of the Tian Shan range form a district watered by countless streams and rivers, with a fertile soil and having a rich vegetation of grass and trees. This portion of Turkestan embraces part of Ferghana, Zerashan, and Khureninsk and Khokand, both in the subdivision of Sir Daria. Its numerous valleys and hills offer the greatest advantages for purposes of cultivation, while the summits of the mountains are equally suitable for pasturage. The settled population occupies, in particular, the hilly districts, while the nomad tribes are scattered over the vast Sir Daria and Amu Daria steppes. Of these the Kirghis are the most numerous, and they may be computed at 800,000. Before the annexation of Turkestan the nomad inhabitants formed two-thirds of the population, now they are less than half. The settled population presents a great variety of races, Iranian, Mongol, and Turk. The most important of these are the Persians, 200,000; the Uzbeks, 200,000; the Tajiks, 150,000; and the Dargases, 25,000. In the towns are also to be found Russians, Armenians, Arabs, and Jews. The town population is reckoned to be 40 per cent of the whole settled population. Among the principal towns are—Tashkend, 57,000; Khokand, 40,000; Khokand,

34,000; Andijan, 22,000; Namangan, 16,000; and Samarcand, 25,000.

The centre of industrial production in Turkestan is of very limited extent in the mountainous part of the province. Its productions are known in the European market as articles of Tashkend and Central Asia. The trade, properly speaking, distinguishes between different articles, as those of Khiva, Bokhara, and other places, although the articles may be made elsewhere. Both the rural and manufacturing organizations have special features peculiar to Oriental countries. In the rural economy small properties producing a little of everything predominate, and in the same manner in the world of commerce there is not a single house which devotes all its attention to the production of a single article on a large scale. Even the cultivation of cotton is carried on side by side with that of other objects of agriculture. A large part of the arable land is used as meadow, and the cultivators are in the habit of transferring cultivation to fresh lands, in order not to exhaust the soil. Almost everywhere lands under cultivation are irrigated by means of canals. Of 61 million deciatines (the tenth part of their area) 28 are considered incapable of cultivation, and even of being used as pasturage. Thirty millions are only suited for pasturage, and of the remaining three millions, two millions are under cultivation, and one million is used as meadow land. The richest agricultural districts are in the plains of Ferghana, Zerashan, Teshkent, and Angren, which cover about one million deciatines. Wheat and rice are the chief grains under cultivation. Barley, millet, and other grains occupy a secondary place. Among textiles, cotton comes first, then flax and hemp. Market gardening is also very general, particularly in melons and water-melons. Since the establishment of Russian colonies, the cultivation of the potato has rapidly increased. The following statement shows the average annual production of lands under cultivation in thousands of pounds:—Rice, 10,000; wheat, 17,000; djengara, 8,500; millet, 5,400; barley, 3,100; other cereals, 3,600—total 47,900,000 pounds. The nomads themselves raise annually about three million pounds of corn. The cotton crop in the districts which have been named is estimated at 400,000 pounds. In Ferghana 150,000 pounds are raised in addition. The cultivation of American cotton has been begun, and already about 600 deciatines have been planted with it. Horticulture is another important branch of rural enterprise, and occupies about 100,000 deciatines. The vine, apple pear, plum cherry, walnut, and mulberry trees are the most numerous in the orchards. The dried fruits of Turkestan are sent to the most distant markets of Siberia and into the southern parts of Russia. Vine culture is steadily increasing, but does not as yet suffice for more than the local consumption.

Sericulture is the principal industry. It is particularly active in Ferghana, which produces 15,000 pounds of silk annually; in Zerashan, 10,000 pounds, and Khodjent, 3,000 pounds. Chimkent produces 2,000 pounds. Bokhara makes 60,000 pounds of silk, Khiva 3,000, and Kashgar 10,000; so that the total quantity manufactured in Central Asia is about 103,000 pounds. At the rate of 125 roubles per pound, silk gives an annual revenue of about 13 millions roubles. The raising of cattle forms the exclusive occupation of the nomads. Among the most numerous animals are goats, horses, camels, and horned cattle. The present number of animals in Turkestan is computed to be—goats and sheep, 1,810,000; horses, 645,000; camels 382,200; horned cattle, 525,000—total 6,362,200. Fishing, to which the Russians at the mouth of the Sir Daria, near Kazalinsk, and in the Aral Sea, are specially devoted, provides an annual return of about 100,000 roubles. Furs of the wolf, fox, and marten bring in about 550,000 roubles. The mineral riches of Turkestan are not yet developed, with the exception of some oil wells near Khodjent. These yield about 750,000 pounds of oil per annum. The towns of the elevated part of the province are the seats of manufacture. Turkestan is so rich in natural productions that only native articles are used. Before the establishment of Russian power the industries were limited to those produced by hand labour, and the inhabitants employed their leisure in agricultural pursuits. There are now 1,662 factories, or rather workshops, divided as follows:—

	Work-shops.	Work-men.	Annual production in roubles.
Sir Daria ...	720	3,000	1,400,000
Ferghana ...	420	2,000	800,000
Zerashan ...	520	1,000	600,000
Amu Daria ...	2	50	50,000
Total ...	1,662	6,050	2,850,000

The most important factories belonging to Russians are 40 in number, of which 12 are spirit distilleries, with a production valued at 500,000 roubles; five are tobacco factories; seven leather; two for making cotton; one oil; and one glass. Among the numerous small native workshops, those for thread and silk are the majority. Those of Ferghana alone produce more than a million roubles worth of silk, and about 300,000 roubles' worth of cotton goods. It is impossible to compute with any accuracy the production of textiles in other localities, but it is extremely active in every family, which annually supply a large quantity of cotton cloth for the army. It is also impossible to state with strict accuracy what the commerce of Turkestan amounts to. The best-known transactions of the three principal towns, Tashkend, Khodkend, and Samarcand, are estimated to reach ten million roubles, but this estimate probably falls far short of the real truth. The

following table may approximate to the external trade of Turkestan:—

EXPORTS.		Roubles.
To the Fair of Nijni Novgorod	...	5,000,000
To the Fair of Irbt	...	500,000
To the Fair of Krestonsky	...	500,000
To the Fair of the Steppes	...	1,000,000
To Orenburg and Orsk	...	1,300,000
To Troitzky	...	1,000,000
To Petropaulovsk	...	500,000
To Semipalatinsk	...	1,000,000
Total	...	10,800,000
IMPORTS.		Roubles.
From Orenburg and Orsk	...	5,500,000
From Troitzky	...	2,000,000
From Petropaulovsk	...	1,500,000
From Fair of the Steppes	...	2,000,000
From Semipalatinsk and Semiretchinsk	...	1,000,000
Total	...	12,000,000

Besides these avenues of trade Turkestan is in constant commercial relations with Khiva, Bokhara, and Chirchik Kashgaria. The export of Turkestan to these countries amounted last year to six million roubles, while the import was 5,700,000. Since 1866 the commerce of Turkestan has doubled. Among the articles exported to it from Russia in Europe are cotton manufactures, linen, and fancy articles. Turkestan sends back in return cattle and about a million roubles' worth of Indian tea.

AN INTERESTING AGRICULTURAL EXPERIMENT.

[FROM A CORRESPONDENT.]

Of the two explanations as to the meaning of the word "dirt," the scientist's that it is matter out of place and the sharp child's that it is "mud with the wet squeezed out," the former is about to receive a practical exemplification, as far as Bombay is concerned, in the proposed utilization of the city sweepings for the manufacture of artificial manure. The invention is the idea of Dr. S. Cooke, of the College of Science, Poona, who has secured a patent for his system. I have had an opportunity of inspecting the article which is put up in large or small blocks as desired. It is a grey porous substance somewhat resembling pumice stone, but is much more friable; in fact, one of its inventors' claims is that it can be very easily reduced to powder and drilled into the ground with seed at the time of sowing. Dr. Cooke has a convincing proof of the efficacy of his invention in his garden. Five plots of ground of equal area have been planted with the same quantity of *michne*. The first plot has been left unmanured, with the result that the weeds have decidedly the upper hand. Plot 2 was dressed with wood ashes, the result not being very satisfactory. Plot 3 was fertilised by the ordinary process of *rah*, two experienced hillmen coming especially to do the work. The result of this treatment of the soil was an average crop, such as may be seen on the ordinary Hill Farm. Plot 4 was worked with partially burnt horse manure, the result being that too much heat was generated which destroyed part of the seed, leaving what did come up very good, however. Plot 5 was the patent fertilizer drilled in with the seed, and the result is simply astonishing. Whereas, the average height of the plants on the other beds was about 14 inches and the colour of the stems varying from light to medium green, the stems and leaves in this plot were of the darkest and richest green, and of a height of about two feet with magnificent heads of seed. As far as can be judged from an experimental growth under favourable conditions, the result is most conclusive, and there should be, if not "millions," at least "thousands" in the invention. As regards the manufacture on a large scale of this fertilizer, it is to be encouraged irrespective of its agricultural aspect, because it furnishes a means of solving what is becoming daily a most serious problem: namely, the disposal of street sweepings, which in large cities and even in small towns in hot climates, necessitates much thought and care, to render the operation of removal harmless and unnoticeable, a result not yet obtained in Bombay, where the Municipality have to grapple with the serious problem of removing the enormous quantity of nearly 400 tons daily. Eight hundred cubic yards of refuse are daily carted from Bombay, and the question is coming prominently forward, "What are we going to do with it?" At this moment Dr. Cooke comes to the front and proposes that a company be formed to take over the entire sweepings and convert them into a useful and powerful agent for good. The company, if formed, would thus stand in that rare but enviable position of public benefactors, while at the same time having the monopoly of a very money-making speculation. The method of manufacturers and the results of the experimental crops have been seen by most of the principal Revenue and Forest officials, and both the simplicity of the former operation and the results of the latter have drawn forth the unqualified approval of the many experienced gentlemen who have visited the scene of operations. For the manufacture is required—a furnace for reducing the sweepings to ashes, a kiln for abstracting lime, and a mill for roughly grinding bones.

The three materials thus obtained are then put into pits in layers of ashes, limes and bones, water is then poured into the pits, and layers of fresh materials introduced as the contents sink, and in about two weeks the result is a paste mass, consisting almost entirely of salts best adapted for replacing the productive power of poor soils. By mixing charcoal with the raw materials a fertilizer can be produced especially adapted for gardens. As a proof of the commercial success of an undertaking of this kind,

It is known that the sweepings of Manchester, Birmingham and other towns in England are readily disposed of at prices varying from £4 to £8 a ton. Chemical manure is exported in enormous quantities from Liverpool at £12.10 a ton. Taking into consideration the cheapness of the raw materials here, a company should make a large profit at Rs. 20 per ton, and above all it would be a great blessing to Bombay to have the mass of refuse innocently converted into a harmless inodorous compound, instead of being a source of danger and unpleasantness to every one.—*Times of India.*

RATES AND METHODS OF SOWING WHEAT.

RESULTS OBTAINED AT THE INDIAN AGRICULTURAL COLLEGE.

It is pretty well known that the quantity of seed per acre will depend on several conditions, among which may be named the character of the soil, preparation of the seed bed, time of sowing and kind of wheat. It may not be so generally known that the season also exercises a strong influence. The experiments at the college with

THICK AND THIN SEEDING

shows clearly that thick seeding gives the best results when the winter is very severe. In the fall of 1883 a series of plots, extending entirely across the wheat field, were drilled in at various rates as given below, and in 1884 the experiment was repeated. Full wheat was sown on plots both years. The results were as follows:

SEED, ONE TO EIGHT PECKS TO THE ACRE.				
No.	Rate, Pecks.	Yield per acre, bushels.—		
		1883.	1884.	1885
1	1	7.7
2	2	16.4
3	3	25.3
4	4	29.1
5	5	32.1
6	6	33.4
7	7	32.1
8	8	34.8

* Rates not sown in 1881.

In 1883-4—a favourable year—there was a little increase from sowing, more than three pecks to the acre. The entire field that year averaged 25.5 bushels with a seeding of five pecks to the acre. In 1884-5 the thickly seeded plots had a slight advantage in location and richness of soil. Notwithstanding this fact the yield rapidly increases, with the increase of seed up to five pecks; and the plots receiving eight pecks gives the highest yield. The rest of the field in which these plots are located, was sown at one bushel per acre with an average yield of 18.5 bushels. The preparation of the seed bed was very thorough both years and the soil had rather more than average fertility. The thick seeding passed the severe winter and spring with the least damage. Could we know beforehand that the next winter would be as severe as the last we should sow thickly—say six pecks to the acre. In the absence of this foreknowledge, we should sow again only one bushel per acre. On poorer soil and with less thorough preparation than we give, we would recommend five or six pecks of seeds to the acre.

BROADCAST AND DRILL SOWING.

A plot extending across the wheat field was seeded with broadcast seeder attached to the wagon. On either side was a plot of the same size seeded with the drill. The aim was to sow the three plots at the one bushel rate, but the broadcast seeder could not be accurately gauged and sowed not less than five pecks to the acre. The yields per acre were:

	Bushels.
Plot 1, drilled	17.0
Plot 2, broadcast	17.8
Plot 3, drilled	20.9
Average of the two drilled plots	18.95
Grain per acre by using drill	1.65

If the broadcast seeder had deposited only one bushel per acre, as did the drill, I think the difference would have been more strongly in favour of the drill.

The drill secures greater uniformity in rate of sowing and depth of covering. The broadcast seeder will do more rapid work, but is better adapted to the broad farming of the west than to this state.

CULTIVATION OF WHEAT.

A small piece of ground was seeded, last fall, in drills two feet apart. One-half of the area was sown at the rate of one-half bushel to the acre, and the other half at two-thirds bushels per acre. During the growing season this year both plots were thoroughly harrowed three times, between the drill rows. The ground was rich and well prepared before sowing. The wheat made a strong growth in the fall and passed the winter and spring with very slight damage. There was of course a rank growth this season, which caused the wheat (Velvet Chaff) to lodge some before fully ripe. The grain was well filled, however, but the harvesting was rather difficult and the wheat was not quite all gathered. The yields per acre were—

	Bushels.
Plot 1 sown 1/2 bushel per acre	32.05
Plot 2 sown 2/3 bushel per acre	32.18

The experiment will be repeated next year on a part of the field crop, and with wheat possessing stiff straw. We draw no conclusions from this experiment for the present, but would suggest that other farmers try the experiment of harrowing a portion of their wheat and report the results to the *Indiana Farmer*.

—*Farmer's Review.*

THE ELECTRIC TREE OF NEW GUINEA.

We have received the following from a correspondent who is usually reliable, but whose account of the discovery of the Electric Tree is so startling that we almost hesitate to believe it in this instance. We therefore publish the narrative of this marvellous discovery "under reserve":—

"One of the German expeditions to New Guinea has just made a startling discovery. It has, of course, been perfectly well known, and is indeed one of the great principles of modern science, that force, or energy, is not only indestructible, but transformable, as, for instance, the heat energy of steam is transformed into the energy of visible motion by the steam engine, and that again into the form of energy which we call electricity, by the dynamo. So, again, it is, of course, familiar that the peculiar force, whatever it is, which we call vital is partly transformed into weak electric currents along the nerves of men and other animals, an extreme instance occurring in the well known electric eel which gives a really powerful discharge of electricity. Now, hitherto in plant-life nothing of the sort, however possible, has been proved to exist, and the New Guinea discovery is neither more nor less than a gigantic vegetable gymnotus. The scientific interest of the find is immense, and not less, probably, its future practical bearing on the lives of our descendants. The electric eel could scarcely be used as a regular source of electric currents, but the *Elasaria Electrica*, as Dr. Kummel has patriotically named it, can, to all appearance, be readily acclimatized and cultivated, and, if not overdrawn on, will give, if one may use the expression, a steady crop of energy available for all the multitudinous uses, for which modern civilization now uses the dynamo or the battery. It is true that the current given by one tree is, though considerable in quantity, of much lower intensity than is wanted for many purposes; but even if it is found that this defect cannot be remedied by coupling up a number of trees in series without damaging them, science has methods of transforming, with little loss, larger weak currents into smaller strong ones, and there need be no difficulty on this score. The outlook is immense: parks which will form a pleasant recreation ground to the citizens will light our cities almost free of cost or care; our gardens will themselves illuminate the villages of their owners, whilst the very hedge-row trees on our farms will supply the power for agricultural operations in the fields which they surround. I purposely refrain from the greater question of the application of electricity from this source to the general supercession of steam and other motors, but that it will come I have little doubt. However, I have said enough both on the theory and the prospects of the discovery, and cannot now do better than relate in his own words the account given me by Lieutenant Von Immer Gassende, the fortunate discoverer, who is now on his way to Sydney, where he catches the French mail steamer, the *Salazie*, on the 6th October and proceeds to Europe. The Lieutenant, though much pulled down by the dangerous fever he has had, and which is indeed the cause of his return home, is anxious to be again in New Guinea, and to pursue those explorations which have been already so fruitful in result. He is a fine type of the German gentleman and sailor. He said—"It is unnecessary to trouble you with many details of our journey. Dr. Kummel and I, with some half-a-dozen men, left the ship at anchor in a small bay to the east of Cape Della Torre, and at once commenced working our way, as nearly due south as we could manage, over the low jungle covered range which here skirts the coast. We saw for the first two days a few natives of the type prevalent in this part of Papua, with small patches of bananas and other cultivated ground; we were not, however, molested by them, and further on the country seemed absolutely without inhabitants. When we had got some 100 miles inland, a journey which took no less than twelve days' hard work, and had reached an elevation of about 5,000 feet, being, in fact, on one of the northern spurs of the great central range, we encamped for the night in a more open country than we had hitherto seen. Our way in the morning was on an ever ascending slope through park like scenery, not only beautiful

HOLLOWAY'S OINTMENT AND PILLS—Outward indications.—Before the discovery of these remedies, many cases of scrofula, &c., were pronounced to be hopelessly incurable, because the treatment pursued tended to destroy the strength it was incompetent to preserve, and to exasperate the symptoms it was inadequate to remove. Holloway's Pills exert the most powerful powers over the unhealthy flesh or skin, without depriving the patient from fresh air and exercise, and thus the constitutional vigour is husbanded, while the most malignant humors, blood-poison, and skin diseases are in process of cure. Both Ointment and Pills make the blood richer and purer, instead of poisoning it to fall into that poor and watery state so fatal to many labouring under chronic ulcerations.

in itself, but a very refreshing change from our previous experiences. Towards noon I stopped under a large tree which seemed to particularly attract the attention of Kummel, who had been finding all kinds of novelties the whole morning, to take the exact bearing of a high peak which was visible through an opening in front of us. To my surprise, the compass seemed utterly drunk, varying in all directions in the most capricious manner at each movement I took. I called Kummel's attention to this, and he said jokingly that we must have arrived at Sindbad's land. I tried a variety of experiments, and found that, on walking into the open, the disturbances became feebler, but did not entirely cease for some distance. Whilst we were discussing the matter, one of the men, who carried a heavy outlass or machete for clearing the path, struck one of a number of peculiar buttresses which ran up the outside of the tree, splitting off a large slice, and revealing a curious-looking black core some half an inch thick, which formed the centre. Kummel, in his scientific curiosity, ran up, placed his hands on the two ends of the core to look at it more closely, and instantly, to my utter astonishment, gave a yell and rolled head over heels, getting up without his spectacles, and stammering to me that he had had a severe electric shock. One of the men was induced to repeat the experiment with similar results. I had no galvanometer, but improvised one with a length of copper wire, the centre of which I formed into an open spiral round my compass, and on inserting the ends of the wire into the opposite sides of the black matter, the needle was violently deflected, showing conclusively that a very considerable current was passing. Every branch and every twig of the tree, which I can assure you we treated with much respect, presented similar ridges and cores, with the addition of a thicker central one, and I quickly proved that the current circulated through the entire system. How it is kept up, no one can at present tell; but there it is. I am not able to say what the intensity or the quantity of the current might have been, but it was enough to knock you down in a very unpleasant way. We made a lot of more experiments on the tree, and would have cut it down, but it seemed a dangerous job to undertake. We saw a great many more of the same kind farther on, quite a forest, in fact; but I was that night attacked with very severe fever, and, after stopping several days to rest, I found myself obliged to return to the ship, and was then invalided home as my only chance. Dr. Kummel has returned with instruments to take proper measurements of the current, and to satisfy himself as to a number of points. In the meantime, I take home a preliminary memoir, pieces of the wood and core, &c., and seeds which we were fortunate enough to obtain. I am sorry I cannot show you them, as they are in my box on the steamer. The chemist on board says the black substance is a very pure amorphous carbon, giving hardly a trace of ash. Dr. Kummel is much puzzled to account for the existence of this singular tree by any process of natural selection. He says he cannot see how the possession of this system of electric currents could have benefited it. It has certainly however, cleared out nearly every other species of forest tree from its habitat. Yes, I sincerely hope *Elaeagnus* will grow in other countries; it would be a great thing, would it not? The Lieutenant was obviously inclined for more conversation, but his time was up for the steamer, and I was reluctantly compelled to let him go with my thanks and best wishes on his voyage. We shall hear much more of *Elaeagnus*.

ENEMIES OF THE SUGARCANE.

IN India little or nothing has yet been done in the way of protecting its agriculturists from the losses caused by insects. There is a school of forestry at Delhi, and the instruction given there includes some account of the insects useful or hurtful to man, and his industries, and we see references as to individual insects from time to time made to Mr. Wood-Mason. Some years ago Mr. Thompson, of the Forest Department, contributed a valuable pamphlet on the enemies of the forest trees; Mr. Haldane's "All about Grubs" mentions several beetles which injure the coffee shrubs; and Mr. Mother in Ceylon and Dr. Bidie of Madras have added considerably to the existing information regarding them. But India has no reports or compendiums such as in England periodically issue from Miss Ormerod's pen, and the first attempt to furnish a general view of the Indian agriculturist's insect foes has been given in the "Compendium of India," the third edition of which was published at Calcutta on July 5. Yet the millions of the soil of India are afflicted with countless hundreds of gardeners; but they are great sufferers from bugs, and their patients will should win for them all the care which the scientific skill at the

command of Government can bestow. They are in many tribes and of different races, the farmers of recognised superiority being the Chasa and Khisan of Bengal, the Kanbi and Kurmi of the Western and Northern Provinces, the Tamil Vellalar, the Teling Reddi, Kapa, and Kampa; and the Canarese Wahala, the finer garden work being carried on by the Tota-Kara, the Mall, the Kach'hi, the Lodha, and others. We have been led to these remarks by the perusal of a pamphlet on "The Animal Parasites of the Sugarcane," by Hy. Ling Roth (Trübner & Co.). The cane is to be seen growing everywhere throughout British India, and, although used by the people more as a fruit than for sugar-making, takes a prominent place among the garden plants. It receives from them great care, for it is a costly plant to grow, occupying the grounds for many months, requiring a rich soil, with plenty of manure and abundance of water. It is liable to be attacked by several insects, and if, from boisterous winds, the tops become twisted, the growth is checked and the cane rots. The planters of the West Indies, South America, the Mauritius, and Australia, have given much attention to the investigation of the diseases and injuries of the cane, and Mr. Roth has done good service to the planting industry and to science by summarising all that is known of its animal parasites. An examination of growing cane exhibits a variety of animal life which is simply marvellous; and the planter who thinks little of a single parasite ignores two important facts: firstly, that parasites breed most rapidly; and, secondly, that myriads make up for want in individual size. Mr. Roth tells us that a species of *Hoplosternus* is the common chafer of Queensland. Its grub destroys the roots of the cane, causing the leaves to become brown and dry up; the growth of the cane is then arrested, and the first high wind knocks it over. In this manner whole fields of cane are killed. In the early stage the larvae are occupied in gnawing the roots. In November and December the chafers, fully developed, appear above ground in swarms, inactive during the day, but feeding eagerly at night. An ant, the *Formica saccharivora*, is supposed to get at the sweet juices of the plant and injure it. Another insect, the wary sugarcane louse, is known to the Mauritius and Bourbon planters as *Le Pou a Poche Blanche*. It is the *Icerya sacchari*, and occurs also in Queensland, and Mr. Roth supposes that it is milked by a small black ant, *Formica rufa-nigra*, in the same manner as species of aphides are by other ants. He considers the Pou to be a cause of very great injury to the cane. The cane has its enemies in other countries. The sugarcane beetle of the United States is the *Ligyus rufescens*, Le C. It is a stout black beetle, half an inch long, which bores into the stalk of the sugar-cane under ground.

Sugar cane ravages in Grenada are caused by the cane-spittle fly *Dolpax saccharivora*; in Natal by the cane smut *Ustilago sacchari*, a disease analogous to the smut of wheat and maize; in the Mauritius by the *Proceras sacchariphagus*, which Mr. Westwood has supposed may be identical with *Diatraea sacchari*; *Girdling* and *Phimena sacchari*, *Fabricius*. The Borer of the Queensland planters has been supposed to be the larva of this *Diatraea sacchari*. It enters the cane above ground and eats up the heart. It is supposed to be identical with the Borer of the Mauritius, the *Proceras sacchariphagus*. The wire-worm, larvae of the click beetle, are found at the roots of the Queensland cane, but no damage from them has been detected.

Many suggestions have been made for the destruction of these and other insect pests. In this country Miss Ormerod is devoting herself to the investigation of the field and garden and forest enemies of the vegetable kingdom, and has suggested several means for preventing or lessening the severity of their attacks. It has lately been said that many insect marauders are killed or scared away by a kerosene emulsion; a gallon of kerosene is mixed with three pints of water and a pint and a half of milk, and churned into a buttery consistency. This is diluted with twelve and sixteen times its weight of water, and has to be at once applied, because the component parts separate if allowed to stand. W. Bancroft, writing in 1878, mentioned that he had with advantage sown the *Eleusine indica* and *Cajanus indicus* pulse among the sugar-cane fields, with the object of attracting the locusts which destroy the cane louse. On the lands which are cultivated on the rotated system all parasites have to seek fresh feeding ground once a twelve-month or oftener, and are thus kept away for a considerable period, or left to die in the absence of their special food. And the protection of insectivorous birds and bats has been recommended, with the hope of keeping down the pests by their depredations. The most common and yellow blast and black blast are planters' enemies for diseases of the cane which need scientific investigation. — *Overland Mail*.

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucous gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the chest and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or giddiness when rising suddenly from a horizontal position? Are there hæmorrhages from the kidneys, scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty, brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial: the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

St. Mary-street, Peterborough, Nov. 29, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.
Hensingham, Whitehaven, Oct. 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WEBB,

Chemist, Calne.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed) VINCENT A. WILLS,

Chemist-Dentist,

Merthyr Tydvil.

Preston, Sept. 21st, 1883.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said, "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.—I am, dear Sir, yours faithfully,

(Signed)

W. BOWKER.

To A. J. WHITE, Esq.

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA
SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A
WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DYSPEPSIA, ATTENUATION OF BODY, ERECTIONS, LASSITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the sequelæ of a mercurial course."—*Dr R. Martin*.

The late Lord Clyde, writing for a further supply of Wilkinson's Sarsaparilla, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your Essence of Red Jamaica Sarsaparilla cured me of a Torpid Liver; all other remedies failed."—*Earl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Cocoa, Citronella, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Cocoa, Cinnamon, Nutmegs, Fibrous Plants, and other Products, and for Cultivation in the Tropics.

[Published at the Press Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the T. A., as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Re. 18), carriage prepaid. As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to, during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

CALCUTTA:—SATURDAY, NOVEMBER 7, 1885.

[No. 45.]

Health, Crop and Weather Report.

Letters to the Editor.

[FOR THE WEEK ENDING 25TH OCTOBER 1885.]

Madras.—General prospects fair; continue favorable in Bellary and Anantapur.

Bombay.—River still falling in Sindh. Rain but generally light in parts of the Deccan and Southern Mahratta Country; more required for rabi crops in parts of Nasik, Khandesh, and Panch Mahals. *Khari* harvest and sowing of rabi crops in progress in most districts; standing crops damaged by blight in parts of Ratnagiri. Cholera and fever in parts of thirteen; cattle-disease in parts of ten; and small-pox in parts of four districts.

Bengal. Rain has been general in Bengal Proper, Orissa, and Chota Nappore, but in Behar slight rain has fallen in a few places only. Prospects of *amam* and other standing crops are generally favourable, except in the inundated tracts previously reported, and in places in Behar, where want of rain is much felt. Sowing of rabi crops is in full progress, and the crops already sown are doing well. Price of rice has generally fallen a little. Fever is prevalent in many places, but the general health on the whole is fair.

N. W. Provinces and Oudh.—Weather seasonable. A little rain is needed in some places for crops on high-lands. *Khari* outturn is fairly good, and rabi sowings are in progress. Markets are well supplied, and prices generally steady. Cases of cholera and fever continue to be reported from a few districts.

Punjab.—Slight rain in the Dehra Ismail Khan district. Fever still prevalent in the Hissar, Delhi, and Peshawar districts; health elsewhere generally good. *Khari* being harvested; rabi operations in progress. Prices stationary.

Central Provinces.—There has been a good fall of rain in Raipore, which has greatly improved prospects, and these are now favourable everywhere. Prices steady. Fever prevalent in a few districts.

British Burmah.—Cholera slight in three districts, elsewhere public health good; cattle-disease prevalent in one district, slight in six districts, elsewhere health of cattle good. Crop prospects good, except in Thabeinyo and Prome where more rain is required.

Assam.—Weather seasonable. Public health fair; cattle-disease still in some villages. Ploughing operations for mustard and *matk lai* progressing; prospects of crops good. Insects are reported as doing injury to crops in parts of the Sylhet district; tea doing well. Common rice 14 seers, 3 chittacks per rupee.

Mysore and Coorg.—Standing crop in good condition in the Bagalore district; lands are being ploughed for *ryak* paddy cultivation, and a few more good showers are needed for dry crops. Prospects of the season and public health good; 3 cases of cholera reported from the Shimoga district; cattle-disease continues in affected parts of the Malnad district; otherwise cattle in good condition. Prices gradually falling.

Berar and Hyderabad.—Weather clear. Cotton-picking progressing; *khari* crops good; rabi sowings continue. Wheat 22 and *juar* 26 seers per rupee in Amraoti. Fears are entertained of damage to standing crops in Hyderabad; rabi sowings postponed on account of rainfall. General health fair. Prices in Hyderabad—wheat 18, coarse rice 12½, white *juar* 19½, yellow *juar* 24½, and *gar* 15½ seers per current sicca rupee.

Central India States.—Weather seasonable. 65 cases of cholera and 29 deaths in town of Rewah, otherwise public health good. Sowing of opium commenced, prospects good. Prices falling.

Rajpootana.—Fever still prevalent in Abu. Tanks, wells, and health good in other parts. Tea not yet out. General health much better in Marwar, where cholera has disappeared. Crops suffered much for want of rain. Prices rising; rice crop lost in Kherwara, where there has been sufficient rain for rabi sowing. *Khari* outturn one-half in Haroti, where rain is urgently needed for rabi. Fever prevalent here also. Cholera continues bad in Panchpab district. Rabi sowings progressing in Ajmere, where there is slight sickness. Tanks drying and wells decreasing in Dholapora. *Khari* crops damaged in Kerowli, where fever continues. Prices rising. Prospects fair. Health good generally, and prices, except in some places, are steady.

Nepal.—Weather clear and cool. Cutting of rice actively progressing.

TEA-PLANTING.

TO THE EDITOR.

SIR,—I strongly advise "A Would-be Planter" to apprentice himself on a tea-garden in Darjeeling or Assam for at least a year, unless he is inclined to follow your sound advice, *viz.*, "not to launch into tea cultivation with such entire ignorance of the subject."

A QUONDAM TEA-PLANTER.

TOBACCO-CURING AT POOSAH.

TO THE EDITOR.

SIR,—I regret to learn from a letter addressed by the Director of Agriculture, Bombay, to a Parsee gentleman, that apprentices are not admitted into the Poosah farm by Messrs. Begg, Dunlop and Co., the proprietors of this tobacco-growing and curing concern.

S. DATTA.

Editorial Notes.

A CORRESPONDENT asks us to furnish him with information, or the name of any treatise, on the "Discovery of Water." We are not sure what our correspondent means by the "discovery of water;" but if he will be a little more explicit, we shall be if possible, to give him the information he wants.

**

We understand that in consequence of the failure of Messrs. Stanes and Co., and the closing of their extensive coffee-curing works at Coimbatore, some of the leading planters about Coonoor contemplate establishing a similar business at Metapollim, and have already secured the necessary land for the purpose.

**

THE latest news from the tea districts is that blight is very prevalent in most gardens in the Terai. The manufacturing reports from Assam are generally unfavourable, and indicate a great falling off in quantity as compared with the original estimates, but Cachar and Sylhet are having favourable weather both for growth and manufacture.

**

A CASHMERE telegram informs us that the Maharaja has abolished the duties on all exports. It is unnecessary to say that this measure was one much needed, and cannot fail in the long run to improve the revenues. But great credit is due to his Highness for the readiness with which he has introduced an important reform so much in opposition to the traditional fiscal policy of the State.

**

THE report by Brigadier-General H. C. Wilkinson, C.B., on the Soldiers' Industrial Exhibition, held in Calcutta, during November 1884, has just been published. The exhibition was a successful one as regards the articles shown by the several soldiers, and the excellence of the work was proved by the ready sale of the articles. The next exhibition, confined to the Bengal Presidency, will be held at Meer Meer during November 1886.

THE indigo brokers report that they have no alteration to make in the estimates already published, although those for the North-West Provinces may yet prove too high. About 250 chests of Oudh native indigo have reached the market, and the quality is said to be fair; 600 more chests have been despatched. A few boiling musters of European indigo have come to hand, but not enough to justify an opinion of the quality of the crop. The season is sure to be a late one, and the first sales will probably be held about the 15th of November.

We see that the New York Forestry Commission has been stock-taking, and the results of its labours have been published in a report. It is in pamphlet form, and should prove of interest, for its pages are illustrated with some remarkably fine photographs of the devastation caused in the Adirondacks. There is also a large coloured folding map of this region, prepared by Professor C. S. Sargent, showing the virgin and weeded timber, and the cultivated and barren tracts as they now exist. We would recommend a study of this report to our Indian Forest Officers.

ACCORDING to the *Dairy World*, a stock company for the manufacture of liquid cheese is preparing to seek incorporation in New York, backed by German capital. The product will look like maple syrup, and have all the pungency and other good qualities of American cheese. We may therefore soon expect to keep our stock of American cheese in the same way as sauce, and use it in a similar manner. The proposal is certainly ingenious, and if carried to a successful issue, will very likely create a revolution in the manufacture of cheese.

AT a meeting of the American Florists in August last, it was stated by the President, Mr. John Thorpe, that there are at present 2,000 first-class gardeners in the United States, excluding thousands of amateurs. That over 24,000,000 cut roses were sold last year, and something like 125,000,000 carnations; it was calculated that about £40,000 were paid to the Dutch last year for hyacinths and tulips; further, that 700 people are supposed to be engaged in selling florists' supplies, and that there are approximately 2,000 cut-flower sellers. He observed that florists have grown four-fold in ten years, and that catalogues have increased five-fold.

THE New South Wales revenue returns for the last quarter were £1,670,539, showing an increase of £88,926 over the corresponding quarter last year. Taxation yielded £590,750, an increase of £58,553; customs, £468,697, an increase of £38,981. The land revenue shows £250,097, a decrease of £48,225. The receipts for services rendered amounted to £775,879, an increase of £85,470. The revenue for the year ending September 30 reached £7,588,804, or an increase of £817,307 over the previous year. Taxation gave £2,249,720, an increase of £167,710. There was an increase on nearly all dutiable articles, spirits being a notable exception, due to the changes in the law having lessened this year's income. The land revenue was £1,959,588, or an increase of £388,844.

REFERRING to some experiments made in India to test the value of irrigating growing crops, a San Francisco paper says that very "few attempts are ever made in California to cultivate grain by irrigation, it generally being considered too much trouble and expense to justify such a process. It would, however, seem that in dry years, with a corresponding enhanced price for grain, a very fair return might be realized from grain grown by irrigation. In view of the fact that India-grown wheat is already competing in the European markets with that raised in California and other parts of the United States, it would certainly seem worth while to adopt any plan which promises to increase the average yield."

THE question of "Sugar-refining by electricity," says *Sugar Cane*, is in a fair way of being shortly solved. We learn that the inventor, Professor Friend, sails from New York to London, where he intends giving a demonstration in Liverpool, extending over several consecutive days, refining about five tons per diem, in

the presence of witnesses who will see the raw sugar go into, and the refined come out of, the machine. This looks like business. One naturally asks why was not this done in New York? Why was it that the Committee of five gentlemen, of which the president and vice-president of the "Electric Sugar-Refining Company" were members, were not allowed to see the process?

A RECENT issue of the *Bombay Government Gazette* publishes the opinions of experts on the value of the seed pods of the babul tree (*Acacia Arabica*) as a commercial product. It is stated that, tinctorially, the substance is not regarded as of any value, and it is only useful in dyeing on account of the tannic acid which it contains. Comparing the seed pods with tannin in sumach, galls or myrabolans, they contain only a very small percentage of tannic acid. The price of sumach being £16 per ton, these pods would not be worth more than £9 or £10 per ton. It is suggested that the best way to make this product useful would be to extract the tannin from it where it grows, and as probably the bark and even the branches of this acacia may contain more tannin than the seed pods, all could be boiled down together, and a better average yield of tannin obtained.

OUR esteemed correspondent, Mr. S. Datta, of Mohurbhunj, informs us in a letter which will be found elsewhere, that the proprietors of the Tobacco Farm at Poosa in Behar do not admit apprentices into their concern. This is much to be regretted, as tobacco-growing and curing on improved methods in India is of very recent date; and Messrs. Begg, Dunlop and Co. would be doing a service to the country by admitting and training apprentices upon their farm. We do not, of course, mean that they should undertake to do so without remuneration, but on the same principle as is observed in all the other branches of the trade, viz., on the payment of premiums. Those wishing to article themselves should, we think, be admitted on these terms. We hope Messrs. Begg, Dunlop and Co. will be able to see their way to meeting a want much felt in India.

THE Ohio State Board of Agriculture for September, 1885, furnishes the following statistics regarding the crops of that State:—Wheat, bushels per acre, 82; yield as compared with five previous years, 53 per cent. Total amount of this year's crop 21,707,763 bushels; average crop of five years, 41,095,249 bushels. Oats, area as compared with last year, 118 per cent; yield per acre 35 bushels. Corn, area as compared with last year, 108 per cent; estimated yield per acre, 30 bushels. Probable total yield, 112,192,741; average yield of five years, 97,348,891. From the above it will be seen that, as a set-off against the deficiency of 191 million bushels of wheat, the State of Ohio has a surplus of 202 million bushels of oats, and nearly 15 million bushels of corn. This will preserve the equilibrium.

DR. J. E. TAYLOR, Editor of *Science Gossip*, who has recently been exploring in Victorian forests, says that "snakes are gradually getting scarcer in Australia. A war of extermination is being waged against them, which is getting hotter and fiercer every day, for there are more people joining in the attack. The more a country gets cleared for pasturage, the less are the chances for snakes. They are then better seen by their natural enemies, among which, perhaps their most deadly, are the laughing-jackasses (*Ducula gigantea*)—a kingfisher which has taken to killing and feeding on snakes instead of on fishes." Does it not seem strange that, notwithstanding the large sums annually spent by the Government of India in rewards for the extermination of venomous snakes, there appears to be no diminution in the number of these reptiles? It would be worth while introducing the "laughing-jackass" (*Ducula gigantea*) into this country.

ACCORDING to *Forestry*, the High Commissioner of the Island of Cyprus has issued a proclamation calling on the Cypriots to abstain from cutting down trees of any size for the purpose by the Forest Department are only hereafter to be cut down. Formerly a tree of enormous size was felled to

make a trough, using only a hundredth part of the timber; and perhaps the next day another forest-monarch; to make a shovel handle. So for every hundred trees which were standing, seventy-two had been felled, and were left rotting on the ground, while there were only twenty-five seedlings for this number of standing trees. To prevent injury from indiscriminate pasturage by goats, reserves are to be absolutely closed for a certain number of years; and when they are opened, other portions of forest will be closed. Resin, formerly extracted in so barbarous a fashion as to cause the death of the tree in seven or eight years, is not to be gathered till the forests have recovered themselves, after which a proper system of extracting resin may be practised.

From a return which the Italian Government has prepared, in reply to a question asked in the Chamber of Deputies, it appears that there are 4,153,432 owners of land in the kingdom, of whom 2,733,467 are men and 1,399,965 women. Out of this number 682,802 own land alone, and 781,934 buildings only, while 2,668,696 own both land and houses. There are 1,875,238 cultivators of land, while 733,039 are described as independent, and 1,526,155 as following divers professions. The provinces in which the landowners are most numerous are Piedmont, where they number 650,048, out of a population of 3,070,250; Sicily, where there are 510,711, out of a population of 2,927,901; Lombardy, where they are 416,569, out of a population of 3,680,615; the Campagna, where there are 404,670 landowners, out of a population of 2,896,577; Venetia, where there are 341,176 landowners, out of a population of 2,814,173; the Abruzzi, where there are 253,529 landowners, out of a population of 1,317,215; Calabria, where there are 225,545 landowners, out of a population of 1,257,883; Tuscany, where there are 213,879 landowners, out of a population of 2,208,869; Emilia, where there are 183,382 landowners, out of a population of 2,183,391; Sardinia, where there are 163,615 landowners, out of a population of 682,002; Liguria, where there are 137,356 landowners, out of a population of 892,373; and Rome, where there are 120,665 landowners, out of a population of 903,472.

It is always unpleasant to us to 'pick holes' in the columns of our contemporaries, and it is with much reluctance that we are compelled here to notice a want of journalistic etiquette, in one of our exchanges—and one which we value very much—the *Planters' Gazette and Commercial News*. In the number for October 1st, 1885, there are no less than *five* articles from the *Indian Agriculturist*, reproduced by our contemporary *without any acknowledgment whatever*. Four of these are taken *verbatim*, and the fifth, on the "Utilization of Indian Fibres," has been made to do duty as an original editorial with a preamble of the first four lines. The leading article, headed "The West India Packet," is a re-print of our paper—*verbatim*—on "Sugar Cultivation in India" (without acknowledgment.) We must confess to considerable surprise and disappointment at finding a journal of the standing of the *Planters' Gazette*, stooping to gross plagiarism (we can call it nothing else) of such a glaring character. We are always pleased to see the information contained in our columns quoted and made use of by our various exchanges; but courtesy demands that some acknowledgment should be made in return. We had observed on one or two former occasions some of our articles reproduced in the *Planters' Gazette* without acknowledgment, and our attention was drawn to the fact by a friend; but we attributed the omission to an oversight. We cannot, however, pass over the present instance without a protest against such a deliberate breach of journalistic etiquette.

Elsewhere will be found an interesting account of the 'balata' industry in British Guiana. Balata is the product of the bullet-tree (*Simarouba balata*). It is manufactured from the milk which exudes from this tree upon the bark being cut; and, when dried, has a chemical composition, (according to Dr. Hugo Natter, F. R. S.) identical with that of gutta-percha and caoutchouc. It may be stated here that the balata-yielding tree belongs to the natural order Sapotaceæ, to which belongs also the *Donandra Gutta*, known as the Taban-tree,

and which furnishes the gutta-percha of commerce. The Shea, or Calam butter of Mungo Park, is the product of another species. The *Achras Sapota*, or Sapodilla plum, of the Calcutta markets, is the fruit of one of the species of this order. We have several representatives of this genus in India, among which may be mentioned the *Mimusops elengi*, yielding the "khirnee" fruit of the N. W. Provinces and the Punjab; and the *Mimusops kanki* or "mowlsari" of the natives, which bears flowers having an overpowering perfume; its fruit, a drupe, is also eaten. The *Mimusops elengi* is very rich in milk, and it would be worth while ascertaining whether it could be utilized in the manufacture of gutta-percha or caoutchouc. The bark of nearly all the species is bitter and febrifugal, and most of them furnish caoutchouc, while others yield fatty matter. The *Baobab butyracea* produces an oily fruit, which furnishes a kind of butter used in Nepal. In fact, the whole order is remarkable for its varied economic uses. Our contemporary, the *Sugar Cane*, from which we extract the information regarding the balata industry, has mis-spelt the generic name. It should be "*Mimusops*" not "*Simarouba*."

The following is a summary of the health, crop, and weather reports for the week ending 28th October 1885:—

In Madras the weather continues favourable; rain is again reported from all districts, and the standing crops are generally good. The harvest outturn will, however, be below the average in some districts. More or less rain has fallen throughout the Mysore State, where the prospects of the season are now good. Ploughing for *ryssah* paddy cultivation has commenced. The cattle are in good condition, except in the Malnad District. In Coorg prospects continue favourable. In Bombay there has been slight rain in the Deccan and Southern Mahratta Country, and more is required for the *rabi* crops in parts of Nasik, Khandesh, and the Poonah Mahals. The *kharif* harvest and *rabi* sowings are in progress in most districts. In the Central India and Rajpootana States no rain fell in the week under report. In the former agricultural prospects are generally fair, but in Rajpootana the want of rain has seriously injured the standing crops in many places. *Rabi* sowings are in general progress. In the Berars *rabi* sowings continue, but in the Nizam's Territories they have been postponed on account of the rainfall, and fears are entertained of damage to standing crops. In the Central Provinces prospects are now favourable everywhere, and *rabi* sowings are in general progress. Except in the Dehra Ismail Khan District, no rain is reported from the Punjab. The *kharif* crop is being harvested and *rabi* operations are in hand throughout the Province. In the North-Western Provinces and Oudh the weather is seasonable, but some rain is still needed in a few places for crops on highlands. The *kharif* outturn is fairly good, and *rabi* sowings are in active progress. Rain has been general in Bengal, Orissa and Chota Nagpore; but in Behar slight rain has fallen in a few places only. Outside the flooded districts, prospects of *aman* and other standing crops are generally favourable; sowing of *rabi* is in full progress, and the crops already sown are doing well. In Assam the weather is seasonable, and prospects are good. In British Burmah crop prospects are good, except in Prome and Thayetmyo, where more rain is required. The general health is fair in all Provinces. Prices are generally steady, except in Mysore and Bengal, where they are falling.

In our issue of the 30th May last, page 268, we noticed the rules framed by the Madras Government under Section 4 (h) of the Madras Forest Act (V of 1882) regarding the exercise of the permission to hunt, shoot, and fish in the Government forests and lands in the Nilgiri District. The *Fort St. George Gazette* of the 23rd October 1885 now publishes a set of rules under Section 21 (h) of the same Act, for regulating the pursuit of game within the limits of any and all reserved forests of any district in the Madras Presidency. The rules run as follows:—

1. Any person who may desire to hunt, shoot or fish within the limits of any or all the reserved forests of any district shall be bound to take out a license at the office of the Collector of the district.
2. The payment to be made for such license shall be Rs. 5, and the said license shall not be transferable. It will be available only for the currency of the calendar year to which it relates, whether it be taken out at the commencement of, or during the currency of, the year.

3. The Collector may, by notification in the District Gazette, declare that any reserved forest shall be closed annually against hunting, shooting or fishing, for any period between the 1st February and the 1st August, and may modify or cancel such notification, and after the publication of such notification no license taken out under Rule 1 will be held to give authority to hunt, shoot or fish in such reserved forest during the close season laid down in such notification. Provided that it shall be at the discretion of the Collector, in the interests of any reserved forests, to declare it closed against a hunting, shooting, or fishing for the whole of any particular year.

4. The poisoning or dynamiting of water or the setting of traps or snares for game in any reserved forest is absolutely forbidden. The catching of fish by the damming or baling of water is not prohibited.

N. B.—No elephant may be shot at (except in *bona fide* self-defence) by virtue of any license issued by a Collector under these rules. Any person wishing to shoot an elephant, must apply to the Revenue Secretary to Government for permission to do so.

A SEPARATE set of rules under Rule 21, Section 26, of the Madras Forest Act, V. of 1882, have also been published for regulating the pursuit of game in fuel and fodder reserves, grazing grounds, and areas under special fire protection. They are the same as the foregoing, except for a few verbal alterations, and run as follows:—

1. Any person who may desire to hunt, shoot or fish within the limits of any land notified as a fuel and fodder reserve, grazing ground or area under special fire protection, shall be bound to take out a license at the office of the Collector of the district.

2. No payment will be required for such license, but it will not be transferable. It will be available only for the currency of the calendar year to which it relates, whether it be taken out at the commencement of, or during the currency of the year.

3. The Collector may, by notification in the District Gazette, declare that any particular fuel and fodder reserve, grazing ground or area under special fire protection shall be closed annually or in any year against hunting, shooting and fishing for any period between the 1st February and the 1st August, and may modify or cancel such notification, and after the publication of such notification no license taken out under Rule 1 will be held to give authority to hunt, shoot, or fish in such fuel and fodder reserve, grazing ground or area under special fire protection during the close season laid down in such notification.

4. The poisoning or dynamiting of water or the setting of traps or snares for game in any fuel and fodder reserve, grazing ground or area under special fire protection is absolutely forbidden. The catching of fish by the damming or baling of water is not prohibited.

N. B.—No elephant may be shot at (except in *bona fide* self-defence) by virtue of any license issued by a Collector under these rules. Any person wishing to shoot an elephant must apply to the Revenue Secretary to Government for permission to do so.

The words italicised show the difference between the two sets of rules. The saving clause at the end of rule 3 in the first set, has been omitted in the second set of rules.

THE latest published Proceedings of the Agri-Horticultural Society of India contain an account of the flowering of the bamboo. The variety of uses to which this most useful plant is put in India, China, and Malaya is almost innumerable. Perhaps its chief characteristic is that it runs to seed at long intervals—sometimes of even half-a-century, and that such fructification is only the forerunner of extinction of the parent stock. As the flowering of the bamboo has sometimes happened during periods of scarcity, and as the seeds have thus come to supplement the food-supply of the starvation-stricken population in the affected tracts of country, the event is considered a precursor of drought in the popular mind. The most noted occurrence of this sort is perhaps, the seeding of the bamboo in Malda and other parts of Bengal during the famine of 1874, when bamboo-rice played a prominent part in the dietary of starving thousands. We are informed that the appearance of this grain, which resembles oats in some respects, came like the bounteous interposition of Providence to avert disaster. The people of the favored localities used to flock to the bamboo forests to collect the grain, which was ground and prepared after the manner of wheat for girdle cakes, or otherwise eaten

as rice. It will doubtless interest many to learn that this grain is exposed all the year round for sale in some of the bazzars in the hill tracts of the Godavery district of the Madras presidency, where it is treated as a common food product by the indigenous races. This would appear to point to the fact that all the bamboos in that part of the country do not flower at one and the same time. However that may be, we know that the young shoots are used as a vegetable here and elsewhere, and make a pickle highly esteemed by the connoisseur. The medicinal properties of the plant have gained a high reputation wherever it is to be found, the astute Celestial being as great a believer in its virtues as the mild Hindoo.

New uses are being found for the drug cocaine, the active principle of the plant *Erythroxylon coca*, which has attracted so much attention recently in this country. The other day it was reported to have been used most successfully as an anæsthetic, and now the *Lancet* has the following account of its having been used with equal success as a remedy for sea-sickness:—

"In a preliminary report on some observations upon 'cocainum muriaticum' Dr. Manassein, of St. Petersburg, gives an interesting account of the employment of the drug in sea-sickness. He had read of its value in uncontrollable vomiting of pregnancy, and thought it might be useful in sea-sickness. He therefore went this summer on a sea voyage, in order to test its efficacy. Among his fellow passengers were two men and a woman, who were especially prone to the malady. He administered to each of them every two or three hours a teaspoonful of the following solution:—Muriate of cocaine (0.15), rectified spirits of wine (in sufficient quantity), and distilled water (150.0) beginning the administration on starting. That it had a prophylactic effect seems clear, for in spite of very rough weather for a period of forty-eight hours, both the individuals were, for the first time in their lives, free from sickness, and enjoyed a very good appetite the whole time. To a child six years old, who began to be attacked with sea-sickness on rising in the morning, the treatment was so effectual that it was able to play about during the day, in spite of the storm. The child took one tea-spoonful in two doses during the first half-hour, and then half-a-teaspoonful every three hours. Another case was that of a girl eighteen years of age, who had been sick for twenty-four hours before the drug was given. The case being a severe one, she had a double dose every half-hour, with 'truly magical effect,' for after the second dose the patient was able to assume a half-sitting posture, and after the sixth dose she rested, and began to complain of hunger. During the rest of the voyage she remained well, although there was much rolling of the vessel. Similar good results attended the use of the drug in three milder cases; and had it not been that his supply ran short, Dr. Manassein would have been able to make more extended observations. Still, from the experience of these few cases, he thinks it justifiable to infer that in the drug we have a certain and harmless remedy against sea-sickness. In the same communication he mentions that he had found 'cocainum muriaticum' of great service in arresting the collapse of two severe cases of simple cholera, and thinks it desirable to try its action in cases of Asiatic cholera."

Dr. T. CHRISTY, writing in the *Gardener's Chronicle*, on the subject of cocaine, says:—"The *Sethia indica*, having been sent to me under the name of *Erythroxylon monogynum*, is found upon examination to contain a certain amount of alkaloid. The *Sethia acuminata*, which has also been sent to me as a variety of erythroxylon, is a drug that has long been in use in Ceylon as a vermifuge, and I have for some time distributed it in the form of a fluid extract. At that time I was not aware that it had passed under the name of erythroxylon. As soon as further supplies of these two drugs arrive, a therapeutic examination will be carefully made with the alkaloids. I am glad to be able to record some further valuable information of general interest respecting erythroxylon coca."

He here quotes the testimony of Dr. Manassein as to its employment in sea-sickness, quoted above, and goes on to say:—

Dr. G. H. A. Dabbs reports this week in the *British Medical Journal* (p. 473) that he has used cocaine most successfully in four consecutive cases of childbirth, and that it is his intention to use it in future cases.

I can only add that in one American journal that reached me last week, there were twelve notices of the employment of cocaine,

and in no one instance have I as yet been able to trace any ill-effects from its use.

The employment of the *Erythroxylon Coca* has now gone from the barbaric stage of depending for the effect by chewing the leaves (which might be fresh or stale: this means that they might contain hardly any percentage of cocaine, or, on the other hand, they might contain 0.55 per cent), to the employment of the alkaloid where the doses can be most accurately appo-tioned. The solution of hydrochlorate of cocaine with water is always better when made fresh, and it is safe to apply it in any case of pain, even with children, by rubbing it in. It is most easily mixed with vaseline, and rapidly allays pain in the joints. A small quantity of the alkaloid may be put with water and then placed on sugar, and it has a marked effect upon any one suffering with a sore throat. The price having fallen to about 42 per grain, it is quite within the reach of any one.

It would thus seem that there is no limit to the uses of this extraordinary drug.

The result of the measures adopted for the extermination of wild animals and poisonous snakes in British India during the year 1884, shows that the number of human lives lost decreased slightly, viz., from 22,905 in the previous year to 22,425; and that this decrease was common to all provinces except Bengal, British Burmah, and Coorg. As usual, by far the greatest number of deaths were due to snake-bite, the figures being 19,629, compared with 2,795 deaths by wild animals. The lower provinces of Bengal and the N.-W. Provinces and Oudh account for 75 per cent of the total mortality. Tigers caused 831 deaths, wolves 265, leopards 229, and "other animals" 1,266. Under the last head, jackals caused 547 deaths in Bengal alone, and 70 in the N.-W. Provinces and Oudh. Alligators, sharks, and crocodiles were responsible for 123 deaths in Bengal. It seems scarcely credible that an apparently harmless animal like the jackal should prove so destructive to human life, but the victims must chiefly have been very young children. The loss of cattle amounted to 49,672, against 47,478 in the previous year. In their case the largest number was destroyed by wild animals, viz., 47,944, and only 1,728 by snakes. Bengal suffered the greatest loss, viz., 12,397. Tigers and leopards were equally destructive, having killed 19,680 and 19,699 head of cattle, respectively. The number of wild animals destroyed shows an appreciable increase, i.e., from 19,890 in the previous year to 23,775. Professional *shikaris* in Bengal accounted for 495 tigers alone. There is a marked falling off in the number of poisonous snakes destroyed, viz., from 417,782 in the previous year to 380,981, but whether we may infer from this a corresponding diminution of the species is perhaps doubtful. The total amount given in rewards increased from Rs. 1,74,355 in the previous year to Rs. 2,46,525. An important point referred to by the Government of India in their resolution on the destruction of wild animals, is the issue of licenses for the possession of arms for the destruction of wild beasts and the protection of crops. It is said that "licenses should be freely given when necessary" for these purposes, and local Governments are requested to report full particulars as to the number of licenses issued. We notice that in Bombay, 1,418 such licenses were issued during 1884, while in Assam the figures reached 6,791. Hyderabad returns show 4,392 licenses issued. The system of paying rewards for the destruction of venomous snakes does not appear to have been adopted generally. It was introduced into the districts of Mozufferpore, Durbhanga, and Monghyr in 1882, and has worked satisfactorily, the number of snakes destroyed in these districts having increased from 10,934 in the previous year to 16,039. In the Madras Presidency, the entries under this head are blank, and the attention of the local Government is drawn to the subject. It appears to us very desirable to introduce the system throughout the country. As a rule, religious scruples forbid the destruction of snakes by Hindoos; but the prospect of a reward may have the effect of calming such scruples to a certain extent. With regard to the subject generally of the destruction of wild beasts and venomous snakes, the Governor-General in Council very rightly observes that much depends on the degree of personal interest taken in the matter by district officers; and instances are not wanting to show that increased exertions on the part of district magistrates are quickly followed by largely

increased destruction. As an example of this, the arrangements made by Mr. KENNEDY, the District Magistrate of Gorukhpore in the North-West Provinces, are quoted, where, by the prompt payment of rewards, the number of snakes destroyed during the year under review at once rose from 203 to 4,418. This is certainly a very striking instance of what 'personal interest' can do in this direction, and the example of Mr. KENNEDY might well be imitated in other districts with nothing but advantage. Without personal exertion of this sort, there can be little hope of materially lessening the loss of human life by snake-bite and wild animals, and increasing the number of reptiles and wild animals destroyed annually.

GOLD ORE-EXTRACTING PROCESSES.

GOLD-MINING forms an important industry in Southern India, where various Companies have from time to time launched into the business with fluctuating success. Large capitals have been sunk in the attempt to extract the precious metal under various methods having for their object the least amount of expense with the greatest amount of yield. There have been many failures, and but few successes, and these of a negative character. At the present time some mines are being worked at a positive loss, while others can hardly be said to be working with any profit to speak of. We have noticed from time to time the numerous discoveries said to have been made by which the extraction of the gold from the quartz, and the other mineral substances in which it abounds, would be rendered quite an easy matter. But so far as we are aware, most, if not all, of these so-called discoveries have been confined to the domain of speculation. There seems, however, to be a chance of something definite being established as to an improved process for extracting the ore with advantage to the miner. Mr. Bosworth-Smith, the Government Mineralogist, Madras—who has since his arrival from England been endeavouring to ascertain the mineral resources of the Southern Presidency—has been making an enquiry into the process adopted for extracting the metal at the Illithoral gold mine. This is one of the few gold mines which is being worked with anything like satisfactory results. Mr. Bosworth-Smith has submitted the following report, dated 15th September 1885, to the Government of Madras on an improved ore-extracting process, which *primâ facie* holds out a hope that gold-mining may be carried on with profit, and should prove cheering news to shareholders in Southern India mines:—

"Since writing my report upon the Illithoral gold mine, in which I stated that, in my opinion, the process there contemplated was not likely to succeed, I have received an account of a new process, which, in my opinion, would be far superior to the one I then recommended. The method that I suggested was that devised by Platner and is termed the 'Chlorinization process'; but since then Mr. H. R. Cassel, who has works in Verulam-street, Gray's Inn-road, London, has invented a process which is said to be able to act upon refractory ores even better than Platner's process. Mr. Cassel also uses chlorine to dissolve the gold, but this gas is generated in a different way. In the 'Platner process' hydrochloric acid acting upon black oxide of manganese (manganese dioxide) generates the chlorine, the manganese being afterwards recovered from the manganic chloride by 'Weldon's process.' In the 'Cassel process' the chlorine is generated from common salt (sodium chloride), by means of an electric current—the same electric current also depositing the gold as a metallic mud in another part of the apparatus, which seems to resemble a Brookner's cylinder. Thus the anode generates the chlorine whilst the cathode precipitates the metal. The following is an account of the process as performed experimentally before a number of the leading metallurgists in London:—

The gold ore, having been pulverized, and concentrated, is placed in a revolving drum with a quantity of salt water, the drum being of sufficient capacity to hold a charge of about 2½ tons. Inside the drum is a series of carbon electrodes, through which is passed an electric current generated by an ordinary dynamo-machine. Soon after the drum is started, caustic lime is added, in order to neutralize by secondary action the acids which would otherwise be formed and would attack the iron, arsenic, or other metals that might be present in the ore, forming salts of these

metals which would precipitate the gold were their formation not prevented, thus undoing all the previous work. By the electrolytical action the salt is decomposed, and chlorine in a nascent state, as well as oxygen, is given off at the carbon anodes. The chlorine combines with the gold, and forms with it a solution of chloride of gold. From that solution the electrolytical action carries it into the interior of a pipe which is covered with asbestos cloth, and placed horizontally in a revolving drum, the gold being deposited in a finely divided metallic state on the interior surface of the pipe which forms the cathode. Inside this pipe is an Archimedean screw, which keeps the water in circulation, carrying the gold slime into a receiver in which it is deposited by gravitation. The slime is drawn off from the receiver at intervals and dried, the gold being recovered by melting in the usual way. The main object in having a revolving drum is that, owing to its rotations the ores inside it may be constantly brought against the positive electrodes, where the nascent chlorine is generated, and thus become converted into chloride of gold.

Thus it will be seen that the "Cassel process" compares favorably with the Platner in the following respects:—

- 1st. It is adapted to more refractory ores.
- 2nd. No previous roasting of the ore is required.
- 3rd. The chemicals required for the solution of the precious metal are usually at hand, being common salt and ordinary lime.
- 4th. No chemicals are required for the precipitation of the gold from auric chloride.

In my report I stated that the chief points for consideration, before using at Illithorai the Platner or chlorinization process as I there called it; were (1) the price and nature of fuel, and (2) the price of chemicals. If the "Cassel process" were used, the nature of these considerations would be considerably changed, as (1) no fuel would be required, and (2) acids are not necessary, neither are expensive chemicals required. Lime could be brought up from Coimbatore where limestone is abundant (burnt 'kunker' should not be used for this process) and salt should be easily obtained. I would suggest that the Illithorai and Kartary Mining Company should send a sample of ore to Mr. Cassel and allow him to try his process experimentally first; then, if successful, put up at Illithorai a suitable turbine powerful enough to drive the necessary stamps and a dynamo-machine for producing the electric current. If the company have such experiments made, they will learn with a very small outlay whether the reef is worth working at all, for, if this process failed, it is exceedingly unlikely that any other could pay."

The suggestions made by Mr. Smith for testing the value and utility of the process recommended by him, are worthy of consideration and trial, and we commend them to the notice of gold-mining companies. The merit of Mr. Bosworth-Smith's communication lies in the fact that he is a trained and professional mineralogist; and being a Government official carrying out a series of investigations with a view to ascertain, and develop, if possible, the mineral resources of the Southern Presidency, he would not be actuated by any private interests or motives in bringing to notice any particular process of extraction without being satisfied himself of its utility or superiority over others.

THE ENSILAGE COMMISSION.

We have watched very closely the course of events in regard to the enquiry into the value or otherwise of the system of ensilage. We have consistently maintained that the system would prove of inestimable value to this country, and we have expressed certain decided opinions upon the subject. We have, however, been looking forward with much interest to the report of the Royal Ensilage Commission, which is calculated to set at rest the question whether, as a method for storing fodder, and as a food for stock, it is worth any one's while to resort to the system in preference to hay-making, which is dependent upon climatic influences, more or less. We are now in a position to furnish our readers with the following preliminary report of the Ensilage Commission, which may be accepted as embodying the views of the Committee in a general sense. We direct special attention to the portions we have italicised, as bearing out our own views as to the superiority of silage over green fodder as a milk-producer:—

The Commissioners have, up to the present time, held 11 sittings and examined 28 witnesses, comprising among their number owners

and occupants of landed estates and their agents, tenant-farmers, designers and inventors of different forms of silos, or of different systems of applying the necessary weights to stacked or ensiled green fodder, chemists, and authors of pamphlets on the general subject. They have also had the advantage of hearing the views of Sir John Bennet Lawes, whose eminent knowledge of all matters relating to the chemistry of agriculture, combined with the fact that his published opinions on the process of ensilage have been regarded as unfavourable to the system, has rendered his evidence of great value and interest.

The Commissioners have by no means desired to exclude unfavourable evidence; on the contrary, they have endeavoured to induce some of those who were believed to be opposed to the system to give them the benefit of their opinions, but they have as far heard no expression of any decidedly unfavourable views. The evidence tendered has been entirely voluntary, all witnesses attending at their own expense.

The evidence of all those who have practically tested the various methods of converting green fodder crops into preserved food for animals without putting them through any process of drying, such as is necessary in the making of hay, has, without exception, established their claims to a considerable amount of success; and although in some cases the results have been evidently more satisfactory than in others, the advantages which the different operators, one and all, have claimed for their systems seems to show that a nourishing and useful food for animals can be preserved, independently of any drying process, within wide lines of divergence in the details of the methods adopted.

It has been conclusively shown that, by different degrees of weighting and of expulsion and exclusion of atmospheric air from the material stacked or ensiled, different degrees of heat and of consequent chemical change are produced.

The degree to which such chemical changes increase or diminish the feeding value of the silage itself, or its relative value in comparison to the green crop, is, in the present state of knowledge, in great measure a matter of opinion, and careful feeding experiments, conducted with a view to test the exact effect of these changes, will be highly important to a solution of this question.

Silage which has been covered in immediately after cutting, and not again uncovered, has been shown to retain the colour and freshness, although developing small quantities of certain acids indicative of a process of fermentation without any considerable accession of heat. Other silage which has been put in at intervals, and from which the air has not been immediately or entirely excluded, has undoubtedly developed considerable heat, and in this case the colouring matter of the leaves has been less well preserved. Yet in both cases, a useful feeding material has been rendered available, which, in unfavourable weather, would have been practically lost if any attempt had been made to convert it into hay.

Bearing in mind the importance of economy, the Commissioners have inquired into the efficiency of various systems of stacking unchaffed green fodder crops without drying, by which it has been contended that, with a proper system of pressure, the necessity for a silo can be done away with.

The Commissioners are not at present prepared to express any opinion upon the economy of any such system, or to compare its advantages with those which are claimed by the advocates of chaffed and close stored silage; but it seems to be established that a temperature sufficiently high to involve danger of fire can be controlled by a proper and efficient system of applying weight in the stack of green fodder.

The different systems of applying weight have greatly occupied the attention of the Commissioners, but as the quality of the silage does not appear to be materially affected by this question, it becomes simply one of economy, and may safely, for the present, be left to each operator to decide for himself according to the special circumstances affecting the particular locality in which his farm is situated.

Some of the best samples of chaffed silage have been produced with pressure not exceeding 70 lbs. per superficial foot, but the degree to which weighting is necessary or desirable remains to be decided upon the greatest amount of evidence that may become available to us. Good results are claimed to have been obtained by means of weights varying from 7 lbs. to 300 lbs. per superficial foot on the top of the silage.

The experience of dairy farmers does not appear to justify the assertion which has been more or less circulated that dairy produce is in any way injuriously affected by silage as food; on the contrary, much valuable evidence has been received to show that feeding

with well-made slays distinctly improves the yield of milk and cream, and the quality of butter.

Where complaints have arisen of milk becoming tainted, the cause has been in our opinion, traceable to its having been in proximity with strong smelling slage, or with persons who have handled it, rather than to the use of such material as food.

The Commissioners have already heard sufficient evidence to justify them in encouraging the development of the system of storing undried green fodder crops as a valuable auxiliary to farm practice. In addition to other advantages, losses, occurring through weather unfavourable for haymaking, may be avoided, and some crops not hitherto grown in this country on account of the impossibility of ripening their seed (such as certain varieties of maize), may probably be successfully cultivated in certain districts to the increase of our present means of feeding various kinds of live stock on arable or partly arable farms.

Kaim-Jackson, Faunce de Laune, J. C. Lawrence, Peter M'Lagan, Fredk. Marshall, Henry Robinson, Stanhope Tollemache, and Jacob Wilson.

RUSSIAN TRADE IN TURKESTAN.

THE state of affairs on the North-West Frontier has happily another aspect than that which has engrossed attention in India for some time past. The Russian approach to India from Central Asia has hitherto been mainly looked at from a purely military point of view; hence an endless variety of hostile schemes have been attributed to our northern neighbours, all having as their object the invasion of India. Now, however, that Russia actually touches the boundaries of Afghanistan, another, far more interesting and important question has been brought forward for consideration,—that of the probability of a successful opening out of trade between Russia and India through the medium of Afghanistan. Those who have for years past, looked upon Russia as a natural enemy to English rule in India, will probably regard with suspicion any attempt that may be made in this direction, especially if the initiative be taken by Russian merchants. But others, putting aside the groundless fears that have for so long held possession of many minds, will welcome the possibility of the opening out of trade on our northern and western frontiers, even though Russian merchants be engaged therein. Russia has so much room for the extension of her commerce with Central Asia alone, that for this and for other reasons, her trade with India is not likely to occupy much attention, so far as she is concerned, for many years to come. If, however, the Russian Government could be induced to consent to perfect freedom of trade with India, no time would be lost—on this side of Afghanistan—in setting in motion what might prove a very large and lucrative trade. But Russia must unfortunately protect her manufacturers, and in this way questions of duties will arise, the settlement of which, on the basis of free trade, may be difficult to arrange. But the earnestness and eagerness with which the Russian merchants of Baku, Orenburg, and various other places, are setting to work to secure the advantages to be obtained from trading with all parts of Central Asia, indicate early that the formation of trade routes, roads safe from attack by robbers, and the establishing of regular trading operations throughout Central Asia, must eventually lead to extending these routes to India, with results hitherto disregarded, because not perceived, from the narrow and mischievously limited considerations usually given to the current of events in Central Asia. Merv, Sarakhs, and Herat are places that are associated at present in most minds, either with war, or as centres of intrigue, difficulties, and dangers innumerable. The two first-named places are, in the imagination of the many, mere pivots on which the destinies of English prestige in the East must some day turn, from their capture by Russia. Now that both these places are in the hands of Russia, the sun still runs his daily course: no sign of the predicted storms is to be seen; but we hear the voice of merchants asking for facilities for trading. They want roads for their merchandise, and do not anticipate war, or even tumult. The military ardour of Russian officers in Central Asia will probably be no more difficult to restrain than the

warlike spirit that finds utterance in India amongst English officers and with the bureaucracy, so rarely capable of independent thought. The long period of unrestrained exercise of power that Russian Generals have enjoyed in Central Asia, may render them impatient of the limit of Russian advance now reached; but the necessities of the Russian Government, the cost of continuous military movements in Central Asia, and the prospect of putting an end to them for some time to come, will force the Government to stop effectually the aggressive propensities which its Generals and officers indulge in common with our own. The commercial aspect of affairs in Central Asia does not exclude political considerations, nor will it render English statesmen indifferent to the protection of the frontiers of our Indian Empire; but it should prevent us from looking at the altered condition of the people in Central Asia, now that they have come under a rule that establishes some sort of order, as being on that account filled with danger to the peace so long enjoyed in our own possessions in India. It would indeed be surprising if the introduction of good government into Central Asia, should be the signal for war and bloodshed in India. These anticipated disasters are the pure offspring of the fears of our own countrymen in India, or at home, and certainly do not emanate from the Russian Government. There is, so far as we can see, no sufficient reason why the present juncture of affairs on our northern frontier should be productive of aught else but an extension of trade and the promotion of peace and good-will.

A Russian official paper, the *Journal of the Finance Minister*, publishes an important article on the trade of Russian Turkestan. The present administration of the Governor-General of Turkestan is confined to the districts of Sir Daria, Ferghana, Zerafshan, and Amu Daria, which have a total area of 611,000 versts, and a population of 2,335,000 souls. The territory is divided as follows:—

	Extent in square versts.	Settled population.	Nomad population.	Total population.
Sir Daria	416,760	500,000	654,000	1,154,000
Ferghana	87,600	540,000	150,000	690,000
Zerafshan	27,200	360,000	360,000
Amu Daria	86,000	50,000	101,000	151,000
Total	611,000	1,450,000	950,000	2,335,000

Throughout this vast region, the character of the soil, as might be expected, varies considerably, and presents striking contrasts. To the north it is of a sandy nature, and imperfectly watered; but towards the southward and eastward, there is fertile soil, well watered, and with a rich vegetation of grass and trees. Since the annexation of Turkestan by Russia, the proportion of the nomad population is said to have greatly decreased, and where it was before two-thirds of the total population, it is now less than half. Some interesting information is given regarding the various races who now constitute the settled population, which may broadly be divided into three classes—Iranian, Mongol, and Turk. In the towns may also be found Hindoos, Persians, Arabs, and Jews. The system of agriculture has special features peculiar to Oriental countries, and the same may be said of the manufactures. Small properties, producing a little of everything, are common to the former, and among the latter no manufacturer confines himself to the production of any one article on a large scale. The chief cereals under cultivation are wheat and rice, but barley, millet, and other grains are also grown. The grain-producing capacity of the country is indeed very great. The statistics give the following as the annual production of the lands under cultivation—wheat, 17,000,000 pounds; rice, 10,000,000 pounds; djongara, 8,800,000 pounds; millet, 5,400,000 pounds; barley, 3,100,000 pounds; other cereals, 3,000,000 pounds,—total, 47,900,000 pounds. The cultivation of cotton in Russian Turkestan is also a growing and important industry, and already the annual production reaches 550,000 pounds. The cultivation of American cotton has been commenced, but the result is not stated. Horticulture is profitably carried on, and the dried fruits are sent into Siberia and the south of Russia. Vine culture is said to be steadily

* The poud or pood=36lbs. English.

increasing, but the produce does not yet suffice for more than local consumption. Another important industry is sericulture, which is largely carried on. The annual silk production is as follows :—

	Poude.
Perghana	15,000
Zerafshan	10,000
Khodjend	3,000
Chimkent	2,000
Total	30,000

Other Central Asian countries also contribute to the silk industry largely. The following statistics are given :—

	Poude.
Bokhara	60,000
Khiva	3,000
Kashgar	10,000
Total	73,000

This culture brings in an annual revenue of about 13 million roubles. Other industries which also give good returns are fishing, chiefly engaged in by the Russians at the mouth of the Sir Daria and in the Aral Sea, trading in skins, cattle-raising (the exclusive occupation of the nomads), and the raising of oil. As an example of the immense impetus given to the various industries of these regions since the annexation of the khanates by Russia, the following tables showing the number of workshops in existence, will prove of interest :—

	Workshops.	Workmen.	Annual production in roubles.
Sir Daria	720	3,000	1,400,000
Perghana	420	2,000	800,000
Zerafshan	520	1,000	600,000
Amu Daria	2	50	50,000
Total	1,662	6,050	2,850,000

When it is remembered that, previous to the Russian annexation, everything was produced by hand labour alone, the result is encouraging, and seems to hold out a hope of future prosperity. The principal factories and workshops, to the number of 40, are, it is stated, owned by Russians, and they include 12 spirit distilleries, 5 tobacco factories, and 7 leather manufactories. The numerous small native workshops are chiefly engaged in the making of thread and silk, and the work-shops of Perghana alone are said to produce more than 1,000,000 roubles worth of silk, and about 300,000 roubles worth of cotton goods. It has been found impossible to compute the production of tissues in other localities, but it is said to be extremely active in every family. Within the last 20 years the commerce of Turkestan is believed to have doubled, and according to the returns the external trade now stands as follows :—

EXPORTS.	
	Roubles.
To the Fair of Nijni Novgorod	5,000,000
To the Fair of Irbit	500,000
To the Fair of Krasnoy	500,000
To the Fair of the Steppe	1,000,000
To Orenburg and Orsk	1,300,000
To Troitzky	1,000,000
To Petropaulovsk	500,000
To Semipalatinsk	1,000,000
Total	10,800,000
IMPORTS.	
	Roubles.
From Orenburg and Orsk	5,500,000
From Troitzky	2,000,000
From Petropaulovsk	1,500,000
From Fairs of the Steppe	2,000,000
From Semipalatinsk and Semiretchinsk	1,000,000
Total	12,000,000

European Russia supplies Turkestan with all she requires in the shape of cotton manufactures, linen, and fancy articles, and she receives in return cattle, and also Indian tea, to the value of about 1,000,000 roubles. Turkestan also has a valuable export trade with Khiva, Bokhara, and Chinese Kashgaria, which amounted in 1884 to 6,000,000 roubles. Wise men, instead of forecasting nothing but war and conflict between these distant but industrious people and those of India, will look forward to a time when, in spite of every hindrance, there shall have arisen a vast, constant, and profitable interchange of commerce with them by the great developing power of the railway system.

Miscellaneous Items.

THE Indian salt revenue for the first six months of the current financial year amounted to Rs. 2,94,24,000 on 15,109,000 maunds, as compared with Rs. 2,82,01,000 on 14,746,000 maunds during the corresponding period of last year.

We understand that cattle, both in Singapore and in Malacca, have lately been attacked by various forms of disease, and many cattle-owners have suffered serious losses. The presence of a trained Veterinary Surgeon in every district would be an incalculable blessing.

THE assay value of coins and bullion received in the Indian mints in the first six months of the current financial year was Rs. 6,00,16,130, and of that coined and examined Rs. 61,11,22,014. Of the latter the Calcutta Mint did Rs. 2,21,79,192, and the Bombay Mint Rs. 3,89,42,822.

THE value of gold imported during the first six months of the current financial year was Rs. 1,86,69,541, and of that exported Rs. 14,91,645; whilst the value of silver imported was Rs. 6,74,74,945, and of that exported Rs. 31,45,221. This leaves a balance of both metals in favour of imports of Rs. 8,15,07,620.

THE trade of the Punjab continues to flourish, and within the last two years the exports have more than doubled in weight and have nearly doubled in value. The chief feature in the most recent report is the wonderful expansion in the export of oilseeds, which has risen from less than a million of maunds in 1882-83 to nearly 5½ million in 1884-85. The value of this export was over 175 lakhs of rupees, or rather more than a quarter of the whole export trade of the province.

At a recent meeting of the South Australian Corn Trade Association, reference was made to the receipt of a communication from England respecting the short outturn of wheat cargoes from California and Victoria. In the interests of the colony, it was suggested that communications be opened with the Victorian Corn Trade Association. The Chamber of Commerce is to take action to remove any cause of complaint. It was asserted that the late rain had improved the prospects of the wheat harvest in the colony.

A CORRESPONDENT of the *Statesman*, writing from Ghatipore, under date, October 23, says :—The paddy crop is very satisfactory and all that can be desired. Aged people say that they have not seen such a splendid outturn for the last seventy years. At first, vague fears were entertained as to considerable damage to the paddy crop, on account of the late heavy and unusual rains. They have, however, done good, and improved the condition of the crop. Cabbages, turnips, potatoes, wheat, barley, peas, and various other seeds have just been sown. The soil has turned very soft and rich owing to the late *hattia* rain.

A CONTEMPORARY says :—In a recent Resolution of the Finance Department on the subject of the expenditure on Government stores in India and in England, occurred a statement which seems to require a word of explanation. While a large saving was shown by the substitution of Indian brewed beer for imported in Bengal, it was added, "In the return for Madras, however, a loss amounting to Rs. 4,845 is exhibited out of a transaction of Rs. 1,03,282." To people who know of the skill and enterprise with which brewing has been carried on of late years in the Nilgiris, this statement must have read strangely. And, as a matter of fact, it is directly misleading. An examination of the detailed military store expenditure shows that the loss, or most of it, was incurred in the purchase of European beer in the local market—the most expensive of all methods, for which the only excuse is an actual running short of supplies. From the same source it appears that the Madras Government really made a saving of Rs. 43,968 by the purchase of Indian beer in a transaction of a little over a lakh. The Nilgiri beer cost them Rs. 1,03,282, and the same quantity obtained through the Secretary of State would have amounted to Rs. 1,47,250. Looking at these remarkable figures it is satisfactory to know that already rather more country beer is drunk by the British troops in India than English; and as the Madras Government has concluded a long-term contract for the full supply of the troops in that Presidency, there will be less chance of such mistakes in the future.

The Government have, rather against the public expectation, declared themselves against Mr. Smith's proposal for the holding of a Jubilee Exhibition in 1887 at Adelaide. Mr. Smith's motion is in favour of the Government granting £32,000 for the buildings, upon the understanding that private persons will guarantee all other expenses. The Ministry state that the public finances will not justify the proposed grant, ignoring the fact that the exhibition would indirectly largely increase the revenue. A large meeting in the city has pronounced in favour of the scheme; some gatherings in the country have condemned it. In connection with the question of exhibitions, it may be mentioned that Sir Samuel Davenport has agreed to represent the colony as one of the Commission in London for the exhibition next year. His decision has given the most genuine satisfaction.

Selections.

OFFICIAL PAPER.

[SUMMARY OF THE WEATHER FOR SEPTEMBER 1885.]

The chief features in the meteorology of the past month have been the practical cessation of the rains over the greater part of North-Western India, and the passage of a small but severe cyclone from the Bay across the Orissa coast and thence into Behar. Both branches of the monsoon have been more or less unsteady, and the rainfall has been chiefly determined by subsidiary depressions, occasioning thunder-storms with heavy local rain, and (in Bengal) by the larger disturbances noticed above.

Beyond a few showers, no rain of importance fell in the Punjab or the adjacent parts of the North-Western Provinces, either on the hills or plains, after the 7th; and in the Berars, Central India, and Rajpootana, except a few showers, generally of small amount, during the third week, there was scarcely any rain throughout. Similar conditions prevailed in Khandesh, Malabar and Dhulia had only slight and occasional showers and the rainfall was very deficient. In the Indus Valley not a drop of rain fell throughout the month.

From the 1st to the 5th there was fairly general, and in places heavy, rain over Bengal and for some distance up the Gangetic plain, and slight rain in the Peninsula. On the 6th and 7th, rain was restricted to Bengal and a few places in the Central Provinces and the Peninsula. On the 8th heavy showers occurred in the South Canonic, but on the 9th and the three following days, little rain of importance fell in any part of the country. On the 13th showers recurred over the Peninsula, and from that date until the 18th they were fairly general throughout Southern India, Bengal, and Assam. On the 19th and 20th there was no rain of importance throughout the whole of India, and on the latter day a serious cyclonic depression began to form off the Orissa and Ganjam coasts. This cyclone passed over the land probably at about 7 or 8 a.m. on the 22nd. It occasioned heavy rain in its immediate neighbourhood and slight rain over the whole of India, except the North-West; but the heaviest precipitation connected with this disturbance occurred during the 23rd and 24th, when the storm had reached Behar and was breaking up. After the dispersion of this storm, a few showers occurred in different parts of the country; but these became less general, and the only rainfall reported, during the last few days, was from a few places in the Peninsula.

The table of the month's rainfall shows that it was deficient throughout the whole of the Punjab, the North-Western Provinces, the Central Provinces, the Peninsula (with the exception of the Deccan, Hyderabad, Mysore, and Bellary), the Eastern Peninsula, and Ceylon, while it was in excess over the whole of Bengal, from Behar to Orissa, and in Assam and Cachar. As compared with previous months, there is a great improvement in Mysore, Bellary, and the Deccan, but in some other parts of the country the rainfall has been very deficient.

The total rainfall of the season is very deficient in the Indus Valley—particularly at Peshawar,—slightly in the north of the Punjab and at Sirsa; also from Khandwa westward in Central India and Khandesh, and southward in the Bombay, Deccan, and North Mysore. Elsewhere the rainfall of the four months has been up to, or has exceeded, the average.

The Cyclone.—The information respecting this cyclone, which was the most severe storm of the present year, is at present very scanty and, owing to the unfortunate disaster at False Point, all particulars from that most important station are wanting. From newspaper reports it appears that it about longitude 87° 30' E. and latitude 23° 0' N., the barometer read early on the morning of the 22nd as low as 28.20 inches; but the report received from Cuttack, which, after False Point, was the station most directly in the path of the storm, reports no lower reading than 29.23 inches. The first indication of the formation of the cyclone was given by Diarmid Island, which on the 20th reported a south-east wind and a very rough sea; but it was not till the morning of the 21st, when the wind backed to north-east on the Orissa and Ganjam coasts and the barometer began to fall at False Point, Saugor Island, and Gopalpore, that there was any direct evidence of the formation of a cyclone. After 10 a.m. on the 21st, however, the storm must have advanced and developed with great rapidity, as by 10 a.m. on the following morning the centre was at Cuttack, where the barometer had fallen half an inch. The following telegram was despatched from Cuttack at 7 p.m., 22nd: "Cyclone began 1 a.m., reaching greatest velocity at 9; a break at 14.30. Wind still blowing with greatest violence." After leaving Cuttack

the storm rapidly decreased in intensity, and travelled quickly north-westward. The centre lay between Gya and Benares on the 23rd, and was almost indistinguishable on the 24th. As the intensity of the storm decreased, the rainfall appeared to increase. Before reaching Behar, the surrounding precipitation, though heavy, had not been exceptional, but on the 23rd and 24th, the following amounts were reported from Northern Bengal:

	Inches.		Inches.
Darjeeling	13	Goruckpore...	84
Purneah	9	Dinagapore	6
Patna	4½		

With the exception of a few places in the Peninsula, the average was everywhere above the average of the month. This excess was greatest (between 0.05 inch and 0.08 inch) with the exception of which ran east and east-north-east from Guzerat across Central India, the south of the North-Western Provinces, and the Central Provinces to the Orissa Coast. On either side of this band the amount of the anomaly decreased, diminishing to + 0.17 at Peshawar and to - 0.51 inch at Mangalore. The difference of temperature from the average in Northern India was somewhat irregular; but on the whole, September was a cool month, particularly in Bengal. In the central parts of the country, in the Peninsula, and also in Burmah, on the contrary, temperature was in excess. Humidity was below the average almost everywhere, the principal exceptions being North and East Bengal and a few places in Madras.

The following table shows the amount of rain and the difference from the average during the month of September according to districts, as far as is indicated by the telegraphic reports:—

DISTRICTS.	Average rain fall in September.	Difference from the average in September 1885.
Punjab, West	3.54	-0.88
Punjab, East	4.28	-3.02
North-Western Provinces, trans Gangetic	7.43	-2.39
North-Western Provinces, cis-Gangetic	6.10	-4.75
Behar	7.33	+7.90
Northern Bengal	14.46	+8.44
Assam, Cachar	11.18	+4.84
Lower Bengal, Chota Nagpore	10.33	+0.76
Orissa, Northern Circars	7.94	+0.10
Central Provinces, South	9.66	+7.01
Berar, Khandesh	5.41	-2.27
Rajpootana, Central India, Saugor, and Nerbudda	6.33	-5.35
Sind, Gutch	1.16	-1.16
Guzerat	5.12	-4.26
Koukan	10.97	-0.75
Deccan, Hyderabad	5.51	+2.30
Malabar	10.93	-4.85
Mysore, Bellary	4.96	+3.19
Karnatic	3.63	-0.60
British Burmah	18.87	-6.84
Ceylon	4.77	-2.49

W. L. DALLAS,
Asst. Meteorological Reporter to the Govt. of India.

THE DECOMPOSITION OF MILK.

[BY PROFESSOR SHELTON.]

THE decomposition of milk, as of anything else that is susceptible of decay, is a dissolution of partnership, so to speak, between the different elements of which the decomposing substance is made up. The elements begin to assume new forms or conditions, and to enter into new arrangements or combinations; some of them, being of a volatile character, escape into the air, in the form of gases which, when the decomposition is in an advanced state, are commonly more or less offensive to the smell, and the rest are so far changed as to leave but little resemblance or no resemblance at all to the original compound. There is a separation of the solid from the liquid, and of the gaseous from both; they all become chemically dissolved, as we may say, individually and collectively, and enter into new combinations when they are free to act in accordance with the natural laws to which they are ordinarily subject. Milk is well-known to be one of the most quickly decaying things we are acquainted with in every-day life, perhaps more so than any other, and various precautions have to be taken with it, in order to keep it fresh or undecomposed, until its most valuable constituents have been extracted and put into a form, as in cheese and butter, which arrests the process of natural decay.

We do not at present fully understand the subject of the decomposition of milk, but it is known to be brought about by the action of micro-organisms of one kind or another, known as bacteria, bacilli, micrococci, &c. It has been demonstrated by German scientific men that milk may be preserved antiseptically—that is, without the aid of any kind of preservative; and this view of the case goes to show that the reason why milk is so quickly perishable is not found in any inherent property it may contain, but because it is a congenial food, so to say, for the fermentative organisms, which are the active decay agents in respect of substances that are rich in nitrogen. But in order to preserve milk in this way, greater care is necessary to be taken than can possibly be forthcoming on the part of those who are practically

engaged in dairy work. The micro-organisms which operate in the decomposition of milk are found floating in the air in myriads, and in order to preserve milk antiseptically, it must be kept wholly and absolutely away from these organisms, or they from it. If none of these organisms are allowed to gain access to the milk after it is taken from the cow, the milk will remain sweet and unchanged for a considerable time; but when we consider that all atmospheric air is naturally full of them, it becomes obvious that to keep milk wholly away from them is a difficult matter, involving a process of air-purification, and of rigid care in transferring the milk from the udder of the cow to a vessel containing the purified air and none other.

Milk turns sour and decomposes, because the germs spoken of are not kept out of it. They are present in the air, and take possession of the milk the moment the chance is offered to them. Sour milk is found to contain them in abundance, and a small portion of such milk will cause fresh milk to turn rapidly sour, if the two be mixed together. It is the little leaven leavening the whole lump—parallel as true as it is admirable, and scientifically correct. Hence it will be seen how necessary it is that all vessels used to contain milk should be carefully cleaned each time after using them. The fermentive germs may be destroyed if the milk be heated for an hour to 70 degs. Centigrade, or 158 degs. Fahr.; or the same end may be accomplished by a temperature of 100 C., in three-quarters of an hour; but other germs will quickly introduce themselves into the milk as it cools, and the heating process will have to be repeated to keep the milk sweet day after day, and for an indefinite time. To boil milk, however, is not to improve it, save in respect of those decay-germs. Boiling precipitates the serum and albumen, makes the milk less easily digestible, and, in the process of cheese-making, reduces the rate at which rennet brings about coagulation of the curd. These undesirable effects are comparatively unimportant in degree, no doubt, and not comparable to the good which the boiling does in reference to the preservation of milk. Milk was intended by nature to be conducted from the teats of the parent into the stomach of the offspring without coming into contact with the air, and hence it is that the boiling of milk does good in killing the germs that milk absorbs from the air.

An interesting series of experiments might be made on milk in reference to cheese-making; and also to butter-making, but especially to cheese-making, with the view of determining the effect which these micro organisms have in the process. We know that really good cheese cannot be made from tainted milk; and yet all milk from which cheese is made contains the germs which bring about the tainted condition. We know, too, that the process of cheese-making is identical, up to a certain point, and differing only in rapidity, with the process of digestion in the stomach of a calf—that is, the milk is coagulated in both instances by pepsin. But no one has yet demonstrated the difference in the coagulum of milk that has been exposed to the air, as in cheese-making, as compared with that of other milk that has not been so exposed, as in digestion. Such a demonstration can only be made on a small scale where an ordinary atmosphere prevails; if indeed it can be made at all, for there would be immense difficulty in completely excluding the one sample of milk wholly apart from the influence of atmospheric germs. We are consequently utterly deficient in experimental data as to the effect of these germs on the cheese, for no cheese was ever yet made, so far as I know, from which their influence was wholly excluded. But the experiment might conceivably be made by taking a given quantity of milk up into the higher Alps, for example, boiling it there to kill the germs, and then making it into cheese; for in the higher Alps the air, as Professor Tyndall found, is naturally free from the germs of which I have spoken. It is to be hoped that our German friends will undertake this experiment with two equal samples of milk, one to be made into cheese in the valley, and the other high up in the mountains.

It may be said that we have no milk, obtained in the ordinary way, in which it is brought instantly into contact with air, that does not contain some of the micro organisms to which reference has been made. One variety of these organisms, acting on the sugar of milk, produces lactic acid; and the curdling of milk in the process of souring is the result of the action of the germs on the sugar of milk, which produces lactic acid, the acid in turn operating on the caseous element by way of precipitation. Other bacilli, which do not act directly on the sugar of milk, operate instead on the lactic acid, and produce butyric acid; and in this way we have butyric acid as a successor to lactic acid, the product of butter being injured in the process. Others, again, operate in the casein of the milk, producing a kind of fermentation which depreciates the flavour of cheese. I have spoken of the purity from organisms of the air of the Upper Alps, for the higher we ascend from the valleys, the smaller become the numbers of the organisms in it; and in connection with this natural fact it would be pertinent to predicate the peculiar excellence of Gruyere and Emmenthal cheese, the best of which is made in some of the high passes and slopes of the Alpine range, the air of which is comparatively pure as compared with that of the valleys. It is beyond doubt that the germs in question perform functions in the dairy, whose importance is far greater than people have any idea of, and from this we may fairly argue the need of scrupulous cleanliness, in order to reduce, as far as may be, the mischievous effect of the decay agents which are employed in Nature's laboratory.

It must be remembered that milk decomposes soonest at about the natural temperature of it, under the influence of the agents to which it is subject, and that cooling or heating of milk each retard its decay. From 95 degs. to 108 degs. Fahr., or 35 degs. to 42 degs. C., supply temperatures at which bacilli are most active. The heating of milk, as we have seen, destroys the germs; and the cooling of milk greatly reduces their potency, until at a low temperature their vitality is entirely suspended, though not destroyed. There are three courses open—1, to keep

the germs out of the milk; 2, to destroy them by heat; and 3, to suspend their vitality by cooling. The first is only theoretically practicable, save in a chemist's laboratory; but the other two are within the reach of any dairy operator. The introduction of the germs into milk is lessened in volume by keeping all vessels scrupulously clean, in which event the bacilli obtain access only from the air, and not from particles of old milk which may otherwise adhere to the vessels. Cooling the milk, too, has the effect of reducing or entirely suspending the activity and multiplication of the germs, for they are reproduced rapidly and in vast numbers at a suitable temperature in such a congenial fluid as milk. Not only the vessels which contain the milk, but also the rooms which contain the vessels, should therefore be kept clean and cool, in order that the germs may have no lurking places, and no suitable temperature in which to breed and multiply.—*North British Agriculturist*.

THE BALATA INDUSTRY OF BRITISH GUIANA.

THE following interesting account of this new industry, taken largely from the Report of Mr. J. S. Jenman, Superintendent of the Botanic Gardens at Georgetown, we copy from a recent number of the *South American Journal*:—

Many causes have retarded the development of the colony, notably want of population. But the extraordinary growth of the system of importing population and thereby labour is remedying this cause, and will in time, it is hoped, remove it. The system is keeping pace with the progress of the colony, and will continue to do so. Another cause is the entire devotion to the cultivation of sugar. The Guianese, from the planter to the negro labourer, are, practically speaking, monomaniacs. All their eggs are in one basket. The recent severe depression in the sugar market has forcibly illustrated the danger of this policy. To say that the colony has been brought to the verge of ruin is an exaggeration. Ruin has, however, stared the colony in the face, and may in the future accomplish what it has recently threatened, if the colony does not take the lesson to heart and develop its other resources. Herein is ample room for the employment of British capital and the exercise of British enterprise, energy, and industry. As our readers are aware, the cultivation of sugar is confined to the mud flats of the sea coast and along the banks of the rivers. The forest interior, save by a comparatively few woodcutters, is unutilized, its wealth and resources undeveloped. It is to one of the products of the forest—balata—we would now desire to draw attention. Balata is the milk exuding from the bullet tree (*Mimusops balata*) upon the bark being cut, and when dried has a chemical composition, according to Dr. Hugo Nutt, F. R. S., probably identical, with that of gutta percha and of osanthonia. Intrinsically it is the most valuable substance of the kind known, but the fact of its not being placed in the market in sufficient quantities precludes its use. In Dutch Guiana an American company has obtained a large grant of forest, and is obtaining at 50 cents per pound for balata, with the assurance that the price will be considerably increased if a permanently sufficient supply is forthcoming.

British Guiana affords excellent facilities for the pursuit of the industry. About 100 miles of the low alluvial forest region of Berbice, on either side of the Canje river, is thickly studded with belts of bullet-tree. The hardy and plucky Dutchmen pushed up the Canje and worked estates there, but these, after emancipation, fell into the hands of negro communities, who in keeping with their habits, let the estates ruin, but who still inhabit the scattered villages along the banks of the river. It is these people, aided also by negroes who come under contract from the mouth of the river, who collect the balata. A quarter of a century since the industry did not exist. Scarcely of India rubber led to the value of the milky secretion of the bullet tree becoming known. Messrs. Silver and Co., of London, were among the first to recognise its utility, and as with all new products, it has experienced varied fortunes. That it has not won its way in the market is due to the fact that it has not been produced sufficiently. It is with the hope of stimulating inquiry into the industry that we subjoin a few particulars gleaned from an exhaustive report upon the subject to the Government of British Guiana by Mr. G. S. Jenman, the accomplished botanist to the Government. The bullet-tree is a large forest tree, reaching to a height of 120 feet, with a trunk 30 to 70 feet long and 4 to 5 feet in diameter, said to range from Jamaica and Trinidad to Venezuela and French Guiana. It is allied to the gutta percha trees of the Malayan Archipelago, from whence comes the present supply of gutta percha.

The bark is about half an inch in thickness, and bears deep parallel fissures about an inch apart, and with longitudinal fissures. The wood has a red tinge, and is one of the hardest and densest the forest yields, and squares up to 3 feet 6 inches. Says Mr. Jenman:—

"The trees are more plentiful in the depths of the forest than near the rivers, hence the creeks form arteries to the balata grounds. Several of the creeks on both banks of the Canje are instances of this. The woodcutters regard the bullet-tree as inexhaustible; in the interior of the forest it exists in profusion, and abundance lies beyond the reach of the balata collectors as they at present conduct their operations. As the trees near at hand become exhausted, they will no doubt alter their habits, and make clearing as drying places in the heart of the forest, but now they are under the obligation of returning to the settlements on the creeks with the milk they have collected to dry. Under this necessity they can at present only penetrate about two days' journey, but so far as they have explored, they report there is no diminution in the abundance of the tree. The forest at this depth of course has never been touched by woodcutters, as for convenience in getting their timber out, they have

to confine their operations to the banks of the river and creeks, rarely going in more than a mile or two."

Many of the giant bullet-trees, Mr. Jenman does not doubt, have braved the vicissitudes of fortune for hundreds of years, nor should he regard it as improbable that some even saw the birth of the Christian era. He himself shall describe the manner of collecting the balata:

"I have mentioned that the river inhabitants are of slave descent. They are consequently negroes. The collectors who come from other quarters are of the same race. They are typically hardy, well-built fellows, capable of heavy work and possessing great powers of endurance. As they meet in the early morning while the settlement was still thinly enshrouded in the mist which the sun just rising over the forest was beginning to dissipate, equipped for their work, I had frequent opportunity to note at once and the same time their physique, dress, and the tools and appliances required in the trade, as well as in my intercourse with them in the forest. Their garments are few, and if they afford little protection from inclement weather, they are adapted not to impede their movements in the forest. They consist usually of a cap that fits the skull and forehead tightly; a thin singlet over the body, also skin-tight; and a pair of Osnaburg trousers that reach just below the knees. The feet are bare. Around the waist a belt is worn which supports the trousers, in which a sailor's snath-kulfo is fixed, naked; and dangling by a short piece of string is a bamboo tube about 4 inches long and an inch thick plugged and inverted to keep out rain, containing matches. In the right hand a outlass is held by the handle with which the holder, as he stands waiting, chops idly at the nearest stump or tree. Over the left shoulder is an axe, on one end of the handle of which is strung two or three goobees in which the balata milk is carried home from the forest and on the other end the coil of calabash basins used in collecting it. If breakfast is taken it is carried in a covered tin saucepan which hangs by the curved iron-wire handle in the other hand. So equipped, the collectors start for their day's work, and it is surprising with what rapidity and ease in spite of their very cumbersome impediments they thread their way through the thick forest when the ground is at all fairly good for walking. The axe is required for felling trees, and the outlass for making the channel in the bark by which the milk is obtained. The outlass is a large instrument twenty-two inches long, curved and rather wider at the outer end, where it is about three inches deep. The axe is the ordinary American kind used by woodcutters. The goobees are natural bottles, the size and shape of an ox bladder, holding from one or two gallons each. They are produced by a gourd—*Lagenaria vulgaris*—which grows in the sand at most Indian settlements, much like pumpkin vine. A hole is cut, about two inches in diameter, near the scar where the stem was connected to the fruit, and the contents of seed and pith scraped out by inserting and twisting a piece of stick or other sharp instrument. This leaves a strong hard shell which for its protection, and as a means to affix a handle is then laced in an open network of mamourie—the split stems of a climbing *Cariduridia*—to which a rather long curved handle of the same material is attached that enables it to be carried over the shoulder of the collector. On the return journey they are balanced by being hung before and behind, usually two each way, and the rapid traveller has to be careful that he does not slip, make a false step into one of the coquerite pit-falls, or trip into collision with a tree, for they are easily cracked by a blow thus given, and the milk at once escapes. When filled the orifice is stopped by a cork cut from the bullet-tree bark, round the edges of which clay is rubbed to prevent any leakage by jolting on the way. The calabashes—*crenato cufito*—basins are prepared much in the same way, only in their case the fruit is split in two, and the pith and seeds then removed. In being divided some of them crack and break unequally, but all the pieces large enough to hold any milk at all worth considering are saved for use. For carrying, the calabashes are threaded together by a hole bored just under the rim; but sometimes they are taken in a bag.

These are generally the only appliances required in the forest for collecting, but in some cases ladders are used for reaching higher up the trunks of the trees that are bled standing than the collectors could reach from the ground. These are made on the spot when required. They are very rough and temporary constructions consisting of two poles from ten to twenty, or rarely thirty feet long, connected by two or more cross-bars, the steps being tied on or made of bush-ropes laced to and fro. From their rickety character accidents sometimes occur in using them, and sprained limbs or ribs are the result. For drying the balata at the settlements shallow trays are employed. They are made of wood, are four inches deep, 18 to 24 inches wide and 2 to 4 feet long. The joints are sealed to prevent leakage by drying a film of balata over them. Oil, grease, or soap is then rubbed over the surface to prevent the milk sticking as it dries. At stations where balata is largely purchased special drying sheds are erected. These are open-roofed thatched buildings, with open sides. A floor, about 2 or 3 feet from the ground, is made of crossbeams upon which the trays stand. Down the middle a passage is left, so that each tray can be conveniently reached for taking off the sheets of balata as they dry, either from the inside or outside of the building. Where a smaller quantity is dried, the trays are arranged around the open sides of the dwelling-houses, kitchens, &c., just inside the eaves. Two or three feet above the trays, horizontal wooden bars or lines of bush rope are stretched, on which the sheets of balata are hung to drip as they are taken out of the trays, when the underside is still in a milky fluid state. When the milk accumulates faster than the means of drying will

At every house and settlement on the river every tree near at hand—even coconuts, coquerites and other palms—has been shipped in like moments, or by various for practice, in the manner the bullet trees are bled.

accommodate it, barrels are used to receive it till the trays become vacant."

At present the collectors often adulterate the balata by the addition of water and other substitutes to increase its weight. What is really wanted is British capital and British supervision. By this means the industry could be systematized, and a sufficient supply of balata placed in the market to ensure its use. That it is a lucrative industry of the future, there can be little doubt. Who will lead the way in making it a lucrative industry of the present?—*Sugar Cane.*

DISSOLVED PERUVIAN GUANO.

The following letter will interest our planters:

"Woodford Lodge" Estate,
Trinidad, 11th June, 1885.

Messrs. A. CUMMING & Co., Port-of-Spain,

Dear Sirs,—Having asked me to state my opinion as to the merits of Messrs. Ohlendorff's "Dissolved Peruvian Guano," I do so now.

I first applied a large quantity on the St. Clair Estate, Arica, in 1881, to both plant canes and rattoons, at the rate of 4 cwt. per acre. The result obtained in 1882 from the canes so treated was satisfactory; the crop, 774 hds. being the largest that that estate has made either before or since. The average yield per acre was, as well as I can remember, nearly 2 hds. Subsequent, while managing the St. Clair Estate, I applied other manures, but never obtained from their application the pleasing results which accrued from the use of Ohlendorff's Guano.

Last year (1884) I obtained from you 58 tons of the Dissolved Peruvian Guano (Ohlendorff's), which I applied to the canes of this estate (Woodford Lodge). The application, both as regards mode and quantity, was identical with that pursued at the St. Clair Estate, with a result even more gratifying, the Crop (830 hds.) was obtained from 146 acres plants and 230 acres of rattoons—50 acres of the former were planted only thirteen or fourteen months before they were reaped, and I gave an average return of 3 hds. per acre—nearly all these canes had no other manure than the Dissolved Peruvian Guano.

I found the juice very rich in saccharine, weighing as high as 11 degrees Brix. I recommend as early an application of this manure to both plant and ratoon canes as possible, for I found that the fluids which received this manure ten months before cutting, gave a ripper and consequently a heavier cane than those which I manured later.

For rattoons I advise two applications of 2½ cwt. per acre each, with an interval of ten weeks between each application.

For plants I think one application of 4 cwt. per acre, applied when the young sprouts are two or three months old, will produce a favourable yield.

I have ordered from you 60 tons of this manure for crop 1886, so persuaded am I that it is the best and safest fertilizer I have yet met with.

I am yours faithfully,
(Signed) S. HENDERSON.

—*Sugar Cane.*

THE VALUE OF TIMBER AFFECTED BY SITE OF GROWTH.

In the course of a lecture "On Timbers and their Uses" before the Chamber of Manufactures at Adelaide, South Australia, Mr. Mack gave several telling instances of the importance of the above theme. In that colony it was necessary to consider the effects of the climate upon wood, and it could not be expected that because certain timber stood well in England it would be equally good at the antipodes. Great extremes of heat and cold were very trying to wood, and in a warm climate insects such as white-ants or the marine borer were much more destructive than in places further distant from the tropics. Timbers that would withstand exposure to the weather or the ravages of insects were especially valuable, and of this class red gum and jarrah were the best known and most used for general and outdoor purposes. If the trees and the locality of their growth were properly selected, these timbers were practically imperishable. The red gum from the Mount Lofty ranges was, as a rule, well-grown, straight and close-grained, and of a good colour, though even here there were trees quite unfit for the sawmill. That produced on the Murray Plains was very unreliable, and though the Victorian forests contained large quantities of good timber, so little care had been exercised in the selection of trees that it had been prohibited from use in Government contracts in South Australia. Western Australian jarrah, locally known as Swan River mahogany, which was greatly relied upon in this colony, grew in the south western districts of Western Australia, the vast granite and ironstone ranges south of Perth being covered with forests of these noble trees, thousands of them with trunks as straight as a mast for 50 or 60 feet and from 10 to 15 feet of girth. Great care, however, was necessary in selecting and cutting the trees, those grown on the slopes of the ironstone ranges being the best. The most reliable timber was not always procured from the largest trees, those of smaller growth giving on an average a turn-out of about 200 cubic feet of clear timber. The reputation of the jarrah was fast spreading, and it had been described by standard writers on the subject as unsurpassed where special tests were necessary. The jarrah, also from Western Australia, had come into prominence recently, and gave promise of rivaling jarrah in importance. So far it had not been much used in South Australia for general purposes, but the timber, inspected to the Admiralty (Mr. Thos. Lestell) gave jarrah a very high position. The tensile experiments placed it much higher than jarrah. A piece of each wood

2 x 3 x 30 inches showed about the same specific gravity, and while the jarrah broke with a weight of 11,750 lbs. the karri withstood a load of 23,280 lbs. The averages crushing weight to one square inch was stated to be—jarrah, 3,108 tons; and karri, 5,140 tons. In a list of timbers suitable for shipbuilding purposes, emanating from Lloyd's, East Indian teak was classed at fourteen years; karri, jarrah, oaks from English, Adriatic, Italian, Spanish, Portuguese, and French forests, together with morung, saul, greenheart, morra, ironbark, Penang cedar, etc., were classed at twelve years; whilst other European oaks, white oak, mahogany, Spanish chestnut, and blue gum, pitch pine, larch, etc., are allowed nine years. Baltic pines, spruce, and Scotch fir were placed as low as six years. Singapore cedar was another well-known wood that had been extensively used in South Australia, but it had gradually lost its reputation, owing principally to careless selection in the forests. There was no timber that varied so much as this, the red coloured, close-grained wood being equal to the best jarrah, and much more easily worked, while the light spongy wood was absolutely valueless. The sugar gum from the Wirrahara forests had latterly been brought into use in some of the public works in the colony with fair success, it being a close-grained wood much like the best blue gum, and according to the Conservator of Forests it had very satisfactorily withstood the attacks of insect. Blue gum was very much akin to the sugar gum, and that from the Mount Lofty range was principally used for "felloes," which, if cut from carefully selected and seasoned timber, were unsurpassed. Much of the so-called blue gum imported was very inferior, and cargoes from Corner Inlet and Tasmanian had proved no better than stringy bark. The wood shrank, cracked, and had twisted and had lowered the reputation of blue gum. Ironbark and spotted gum from New South Wales and Queensland were good hard timbers, especially adapted for glider work, and obtainable in lengths up to 60 feet. They were very durable, and capable of sustaining great weights, but were unreliable when exposed to white-ants or marine insects. West Australian tuart was a splendid quality of timber, very heavy and dense in grain. It was unequalled for scantling, and was largely used for the heavy portions of railway trucks, etc. Blackwood was strong and durable, being used for railway trucks and coach-building, especially for wheels in light traps. It bends readily when steamed, and was taking the place of American hickory. Once insects obtained entrance to a building, the timber of which was suited to their palate the result was disastrous, and hence arose the necessity of knowing the woods that they were least likely to attack. For this reason he (Mr. Hack) had particularly noticed the red gum, jarrah, karri, and Singapore cedar, the others mentioned not being so proof either against insects or rot.—*Forestry*.

CORKS AND CORKWOOD.

There exists in the art of bottling no more prominent factor than the cork.

And yet it is extremely doubtful if one person in ten—yea, one in a hundred—of all those who are called upon to handle this useful article, either in connection with bottling or otherwise, has any definite idea of its history, the mode of its culture and preparation, or the multitudinous uses which it is called upon to serve.

To such as are enlightened upon the subject it must always be a matter of wonder what the world did before corks were invented.

Did the ancients have bottles? If so, with what did they seal them? for it is difficult to imagine any article that could fully supply the place of cork.

A glance, therefore, at this subject, viewed from a historical and agricultural standpoint, may not prove uninteresting reading to those whose interest our paper is endeavouring to serve.

First, let us glance at the history of cork.

It is certain that its culture and use was familiar to the ancient Greeks and Romans, though it was not largely employed by them as a stopper. This was owing to the peculiar nature of the bottles employed, which were made of leather, or often of the undressed skin of the goat or kid.

The method of making these bottles was to strip the skin of a goat from over the neck of the animal, leaving it otherwise nearly without holes such as there were, being formed by the legs, and were easily closed. These primitive bottles are used by the Arabs to this day.

In the form of stoppers for general use, corks were introduced towards the end of the sixteenth century, since which time the industry has not ceased to grow in importance.

The bark of all trees consists inwardly of a parenchymatous, or soft cellular tissue, and outwardly of a harder, woody, tubular tissue, the latter generally being more abundant. If the growth of the parenchyma be prolonged and rapid, it will assume a more or less corklike character, as is true in the case of some of the elms, the common oak, and many other trees.

This peculiarity is developed to an exceptional degree in one species of oak, which has been named, from this circumstance, *Quercus suber*. It is the bark of this tree which constitutes the cork of commerce.

The cork oak is an evergreen, growing to the height of about thirty feet; its acorns are edible, and resemble chestnuts in taste. It does not require a rich soil, but, on the contrary, seems to thrive the best on poor and uncultivated ground.

It is principally found in France, Portugal, Spain, Tuscany, the island of Sardinia, and on the African coast bordering on the Mediterranean.

The cork used in this country comes entirely from Spain and Portugal—the provinces of Catalonia and Estremadura in the former, and Alentejo in the latter country, furnishing the most abundant supply.

The Portuguese cork is inferior to the French in quality, but superior to the Italian, being lighter and whiter. Sardinia produces a kind easily distinguished by its color and weight, being pinkish hued, and heavier than many other varieties. It is considered by the English the best variety which can be obtained, but little, if any of it, comes to the United States. In 1861 it was reported that the cork forests of Sardinia and Corsica had been in a great measure destroyed by improper working; but this report, like the anne rumored failure of the peach crop in Delaware, seems to have made little difference in the supply.

France produces the finest grades of cork, especially in Languedoc province and the environs of Bordeaux. The peculiar velvet cork, so esteemed in the bottling of champagne, is the production of those places, and is becoming very scarce, it being feared it will, in time, become unobtainable.

Africa produces large quantities of cork, but of an inferior grade, although the soil and climate of its northern countries seems peculiarly favorable to its propagation. This is especially true of Morocco and Algiers. The causes of this are to be found in the uniformly high temperature and profuse nightly dews, while the dry, warm, open hill-sides are covered with a sufficiency of light soil, peculiarly adapted to the growth of the trees, which attain to a larger size here than elsewhere.

There are said to be 2,500,000 acres of cork forests in Algiers alone, of which about 300,000 are utilized. It is said to be capable of producing as much cork as all the rest of the globe, if the inhabitants could but be persuaded to remain peaceable, and give their attention to agricultural pursuits.

In 1859 an attempt was made to introduce the cork oak into the United States, Portuguese acorns being planted, with this end in view, in Wayne County, Miss. All grew, the largest trees, eleven years later, measuring thirteen feet in height, while the trunks had attained a diameter of eleven inches in thickness, the cork bark being more than an inch in thickness. In 1872 the planting of cork trees was attempted in southern California, but with what success does not appear.

Among the conditions necessary for successful cork culture, climate and soil are of the foremost importance.

In the Mediterranean basin, where it is indigenous, the tree favors altitudes varying from 1,600 to 3,200 feet. It does not flourish beyond 45° north latitude, and the minimum temperature must not be less than 55° Fahrenheit.

It grows best on southerly slopes, which afford a freer circulation of light and air than do flat lands. It requires abundant sandy soil. Planting is usually performed from seed; as a rule the large, sweet acorns developing into the best trees, which yield the finest cork, the small, bitter acorns producing trees of a coarse and inferior nature.

The most approved method of planting, and that which is employed in France, Spain and Portugal appears to be the furrow or "hill" system, which consists in sowing the acorns twenty to forty inches apart, in a furrow between two or more grape-vines, placed at from five to seven feet apart. The sowing and planting are conducted simultaneously, the vines affording the shelter which is so necessary to the cork tree during its early growth. The young trees are thinned out as required so as to afford abundance of air and light to each. About fifty trees to the acre are recommended by the French cork producers, and the production is about eighteen pounds to each barking of the tree.

The distinguishing feature of the cork oak is that the parenchyma forms the mass of the bark, while the contrary is true with nearly all other trees. In the earliest state of its growth it is much more elastic than it ultimately becomes, owing to its containing in the first instance a large proportion of woody matter. The outer casing of the bark is formed during the first year's growth, and does not subsequently increase; but the parenchyma or inner bark continues to grow as long as the tree is alive.

In consequence of this phenomenon, the pressure of the growing inner bark beneath, forces the outer shell to split and peel off in flakes. The substance thus shed under natural conditions is known as "virgin corks." It is very coarse and of woody texture greatly resembling the bark of the California live oak in appearance. Its uses, from its coarse nature, are very limited.

The removal of this outer bark from the tree is fortunately when performed in a judicious manner, unattended with any evil consequences to the tree; on the contrary, the operation seems to hasten and assist the growth of the bark, improving its quality, and at the same time the tree grows more vigorous, and attains greater longevity, trees which are regularly barked being known to live to the age of one hundred and fifty years and upwards.

The age at which the first stripping may be attempted varies with the locality, from fifteen to thirty years, the former being the most general.

The yield much resembles the naturally shed virgin cork, and is commonly included under the same term. Subsequently the barking is repeated at intervals of eight and ten years, the quality improving on each occasion. The second crop is also said to be coarse for any but inferior uses.—*Independent Journal*.

HOLLOWAY'S OINTMENT AND PILLS.—Ever Useful.—The stiffened by illness should take their diseases fully in the face, and as one seek a remedy for them. A short search will convince the most sceptical that there noble medicaments have afforded ease, comfort, and oftentimes complete recovery, to the most tortured sufferers. The Ointment will cure all descriptions of sores, wounds, bad legs, sprains, eruptions, erysipelas, rheumatism, gout, and skin affections. The Pills never fail in correcting and strengthening the stomach, and in restoring a deranged liver to a wholesome condition, in rousing torpid kidneys to increase their secretion, and in re-establishing the natural healthy activity of the bowels. Holloway's are the remedies for complaints of all classes of society.

THE FOREST COMMISSION.

The following questions have been framed for the examination of witnesses at the Forest Commission:—

A.—THE PRACTICE OF RAB.

1. Can you describe variations from the method of collecting, preparing and spreading the materials as described in the "Notes?"
2. Describe varieties of rab and quassal rab other than those mentioned giving points of difference and the explanation of variations, if possible.
3. The "Notes" show that custom varies as regards the treatment of the seed bed. In some localities it is kept unchanged for years; in others the site is yearly shifted, and in cases where the former custom prevails with respect to rice, the latter in the same locality is followed with nachni and other hill grains. Again, in places the seed bed is not touched till after the seed has been sown, while in others it is ploughed and the upper layer of earth scraped off before the rab materials are spread. How do you account for these differences in practice? Is the one wrong and the other right? Or are both justifiable, the differences being attributable to varying circumstances of soil, climate and the like?
4. Ain loppings are considered the best material for rab, after cow dung. How do you account for this opinion? You will notice that the experiments, as far as they have gone, appear to give small support to the superiority of ain. Can you divide the various trees and shrubs used for rab into (1) superior, (2) middling, and (3) inferior? Adduce grounds for your classification.
5. Are the quantities and proportions of the materials, as used in the experimental plots, according to your ideas just and sufficient? How do you account for the absence of accessories in cow-dung rab at Igatpuri and in other localities, if any, where the accessories are not customary?
6. Is leaf rab practised in any locality with which you are acquainted as a substantive variety of rab? If not, how are leaves utilized and to what extent?
7. In the case of sheep-dung rab, why is the manure not burnt as in the case of cow-dung rabs?
8. Do you agree that soil and other circumstances, rather than the character of the rab, determine the variety of the rice?
9. How far do you think the area of transplantation with different kinds of rab can be equalized by the quantity of seed sown? Do the areas of transplantation, as shown by the experiments, harmonize with your experience?
10. How do you justify the necessity of rab?
11. Can you suggest any improvement in the practice generally or in any particular locality?
12. If rab experiments are repeated next season, what alterations in the plan and arrangements made by the Director of Agriculture would you advise?

B.—CLIMATIC AND GEOGRAPHICAL LIMITS OF RAB.

13. How far do (1) the duration, (2) the character, (3) the amount of the rainfall affect rab?
- The notes show that rab is practised in districts with a rainfall as low as 68 inches. Can you name localities with a less rainfall where the practice is prevalent, and can you show that it is not customary in districts where rice is grown and where the rainfall is much heavier? How do you account for its absence in the latter case? e.g., in parts of Dharwar and Kanara? Why is rab used for rice in sweet land and not in salt marsh rice land?
14. Do you think that districts which are exposed to the heavy burst of the South West monsoon especially dependent on rab? If so, why? Again, do you think that those districts which are out of the reach of the north-east rains need rab on that account? How far do you think that the storage of water in tanks makes rab unnecessary?
 15. Do you think that rab could be introduced with profit into localities where it is not now customary?
 16. How do you explain the *dhulwaph* practice of sowing rice?
 17. What relation does *dalhi* or *kumri* bear to rab? Is one the practice of inferior cultivators and the other of more intelligent farmers? Is rab an improvement on *dalhi*? Which is the older form of cultivation? Could rab be substituted in places where *dalhi* is now practised? If not, why not?
 18. In any locality with which you are acquainted, where rice is grown partly with and partly without rab—other than localities where salt marsh rice land causes the difference—how do you account for the gradual disappearance of rab? Do the finer sorts of rice vanish with the rab?

C.—GENERAL.

19. Why are fallows on hill lands and other *varkas* customary? Is exhaustion of soil, or increasing of weeds, or absence of rab materials the cause? Or are there other explanations? Describe as many distinct rotations of crops on hill land as you can, stating the locality.
20. What is the duration of fallow? What are the circumstances which necessitate longer fallows in one locality than in another?
21. To what extent do cultivators utilize occupied *varkas* for the growth of rab materials? Can you suggest any feasible plan by which they could be induced to allot a portion or a larger portion of occupied land to this purpose?
22. Do you think that the poor hill lands now cultivated with nachni and other similar crops pay true rent, in other words, leave a profit to the cultivator after a fair deduction for cost of cultiva-

tion? If so, what proportion of the true rent is absorbed by the assessment?

23. Would you limit the extension of rice and hill grain cultivation? If so, how and to what extent?

24. How far do you think that practically a substitute for rab either by the use of chemical or other concentrated manures can be found?

25. Is rab used for other crops than rice, nachni and varai? Is it ever used for sawa barag, bhaddi and the other smaller millets? Why not? Under what conditions are nachni and varai grown without rab? Are they ever grown on the transplantation when the seedlings are not raised on a rabbed seed-bed?

26. In connection with rab you are at liberty to put to yourself any other question than those given here, and to give your reply; and you are requested to do so.

F. C. OZANNE,
Director of Agriculture, Bombay.

AN AMERICAN PEACH FOREST.

MR. JOHN H. PARNELL, a great American peach-grower, has been letting out some of the secrets of his peach forest, which may have more interest as Mr. John Parnell is the brother of another and more famous member of the family, Mr. C. S. Parnell himself. "In my early days," said Mr. Parnell to the correspondent, "I was advised that there were excellent chances for investment in the South, and especially in Georgia. It was my idea that there located there was money in cotton, so I paid cash down 12,000 dol. for 1,500 acres. To this original purchase I have since added 500 acres, making my possessions 2,000 acres in all. For three years I planted cotton, only to find it a delusion." It was in this fortunate moment that Mr. Parnell made up his mind that there was money in peaches. The great peach forest is described as containing acres and acres of ground, stretching indeed into miles, covered with every variety of tree. The trees, which number 150,000, are planted twelve feet apart, and are kept trimmed to the ground, so that a person standing can pluck the rosy fruit from its fastness. When the first blush comes upon the cheek of the dainty beauties, 100 men, women, and children are set to work, each armed with a flat basket, returning to the rendezvous when the bottom is covered. Thus they keep on day after day until the season is over. The story of Mr. Parnell's venture is briefly this:—He invested 12,000 dol. in his plantation. He has spent over 8,000 dol. since in trees, seeds and labour. Upon this investment he makes from 8,000 dol. to 10,000 dol. a year, and would not sell his peach forest for less than 300,000 dol. Great as Charles Stewart Parnell is as the uncrowned king of Ireland, greater is John H. Parnell, the peach king of America. "I found it necessary to have recourse to English varieties. It was clear that a hard, firm peach which would bear handling would be a good mine. In 1871 I brought from Eng and 6,000 budded trees—the Beatrice, the Early Rivers, and the Early Louise. I have found that these three varieties meet every requirement. I have developed a hybrid, to which I have given the name of Parnell. This peach is destined to rank in the peach family as the Le Conte does among the pears. I secured it from an accidental seedling. I made my first shipment of this peach five years ago when it went off at 25 dol. a bushel. I have now seven thousand trees of this variety. It has a dark red skin, white flesh, and is firm and hardy for shipment. The next is the Foster, a peach of yellow skin, saffron flesh, and firm mould. But one crop in three of this peach however is fit to ship. Of the Amelia peach, dark fleshed and brownish red cheek, I have over 8,000 trees. I have spent much time in experimenting, and believed that I have now solved all the difficulties of this neighbourhood. As old trees die I replace them, and also make a regular annual increase of 25,000 trees."

"The worst enemy of the peach orchard," remarked Mr. Parnell, "is the half-taught horticulturist with a pruning knife. There is no doubt but that peach trees understand the art of growing and should be let alone. The borers will not do as much harm as the man who tries to exterminate them. If a tree yields bad fruit, just cut it down and replant. The principal danger, however, is winter killing, which is a misnomer, because the killing takes place owing to the absence of winter. Where no winter comes the sap never sinks. A sudden cold day chills the tree, just as it does a man. I have fully exploded one idea prevalent, that it won't do to plant a new orchard upon the site of an old orchard. Thousands of my best trees are standing upon ground which has been the site of half-a-dozen previous orchards. Trees set out to the north-east never fail to have fruit. Peaches flourish in alternate years, sometimes one variety, and sometimes another. In 1875 there was a wonderful yield of early peaches. In 1878 the crop was equally good, but in 1879 there was a peach famine, which caught me two ways. The famine in Ireland deprived me of my route, and the famine in peaches deprived me of my income here. In alternate years since, with wonderful regularity, the yield has upheld the theory. The earliest shipment ever made to New York was on the 10th of May, and the latest the 10th of August, when the Delaware crop cuts off the Georgia sales."

"The demand for good fruit has never yet been met. I always have more orders than I can fill. New York is the great market, because it is the distributing point, and always offers regular prices. Philadelphia stands next as an Eastern market. Cincinnati is the great peach depot of the West. I once got 25 dol. a crate in Cincinnati. My heaviest shipment in one day was 900 crates to the New York market. Large quantities I send by freight and small quantities by express. In one year I netted 11,000 dol. This year I have already shipped 1,000 crates."—*Full Mail Budget.*

WHAT IS THIS DISEASE THAT IS COMING UPON US?

Like a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy and has evil forebodings. There is a giddiness, a sort of whirling sensation in the head when rising up suddenly. The bowels become constive; the skin is dry and hot at times; the blood becomes thick and stagnant; the whites of the eyes become tinged with yellow, the urine is scanty and high-coloured, depositing a sediment after standing. There is frequently a spitting up of the food, sometimes with a sour taste, and sometimes with a sweetish taste; this is frequently attended with palpitation of the heart; the vision becomes impaired with spots before the eyes; there is a feeling of great prostration and weakness. All of these symptoms are in turn present. It is thought that nearly one-third of our population has this disease in some of its varied forms. It has been found that medical men have mistaken the nature of this disease. Some have treated it for a liver complaint, others for kidney disease, etc. etc., but none of the various kinds of treatment have been attended with success, because the remedy should be such as to act harmoniously upon each one of the organs, and upon the stomach as well: for in Dyspepsia (for this is really what the disease is) all these organs partake of this disease, and require a remedy that will act upon all at the same time. Seigel's Curative Syrup acts like a charm in this class of complaints, giving almost immediate relief. The following letters from chemists of standing in the community where they live show in what estimation the article is held:—

John Archer, Harthill, near Sheffield:—I can confidently recommend it to all who may be suffering from liver or stomach complaints, having the testimony of my customers, who have derived great benefit from the Syrup and Pills. The sale is increasing wonderfully.

Geo. A. Wobb, 141, York-street, Belfast:—I have sold a large quantity, and the parties have testified to its being what you represent it.

J. S. Metcalfe, 55, Highgate, Kendal:—I have always great pleasure in recommending the Curative Syrup, for I have never known a case in which it has not relieved or cured, and I have sold many gross.

Robt. G. Gould, 17, High-street, Andover:—I have always taken a great interest in your medicines, and I have recommended them, as I have found numerous cases of cure from their use.

Thomas Chapman, West Auckland:—I find that the trade readily increases. I sell more of your medicines than any other kind.

N. Darroll, Clun, Salop:—All who buy it are pleased, and recommend it.

Jos. Balkwill, A.P.S., Kingsbridge:—The public seem to appreciate their great value.

A. Armistead, Market-street, Dalton-in-Furness:—It is needless for me to say that your valuable medicines have great sale in this district—greater than any other I know of, giving great satisfaction.

Robt. Laine, Melksham:—I can well recommend the Curative Syrup from having proved its efficacy for indigestion myself.

Frickheim, Arbroath, Forfarshire, Sept. 23, 1882.

Dear Sir,—Last year I sent you a letter recommending Mother Seigel's Syrup. I have very much pleasure in still bearing testimony to the very satisfactory results of the famed Syrup and Pills. Most patent medicines die out with me, but Mother Seigel has had a steady sale ever since I commenced, and is still in a great demand as when I first began to sell the medicine. The cures which have come under my notice are chiefly those of liver complaint and general debility.

A certain minister in my neighbourhood says it is the only thing which has benefited him, and restored him to his normal condition of health after being unable to preach for a considerable length of time. I could mention also a great many other cases, but space would not allow. A near friend of mine, who is very much addicted to costiveness, or constipation, finds that Mother Seigel's Pills are the only pills which suit his complaint. All other pills cause a reaction which is very annoying. Mother Seigel's Pills do not leave a bad after-effect. I have much pleasure in commending again to suffering humanity Mother Seigel's medicines, which are no sham. If this letter is of any service, you can publish it.

Yours very truly,

(Signed) WILLIAM S. GLASS, Chemist.

A. J. WHITE, Esq.

15th August, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's syrup which he got from me has saved his life.

Yours truly,

Mr. WHITE.

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DEBILITY, ATTENUATION OF BODY, ERUPTIONS, LEASITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the sequelae of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of Wilkinson's Sarsaparilla, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your Essence of RED JAMAICA SARSAPARILLA cured me of a Torpid Liver; all other remedies failed."—*Barl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Cocoa, Ginseng, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at Observer Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the T. A., as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Rs. 1; back copies, 3s. or Rs. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Rs. 18), carriage prepaid.

As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements,

[9 words to line.]

12 lines and under, per Line	0s. 9d. (6 annas)
Above twelve	0 8 (7 " "
Quarter Page, once	17s. 6d. (10 " "

CALCUTTA :—SATURDAY, NOVEMBER 14, 1885.

[No. 46]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING NOVEMBER 4TH, 1885.]

Madras.—General prospects fair; continue favourable in Bellary and Anantapur.

Bombay.—River continues to fall in Sind. Slight rain parts of Dharwar, Belgaum, Bijapore, Ahmednugger, and Sholapore; more rain urgently required for *rabi* crops in parts of Khandesh. Reaping of *kharif* and sowing of *rabi* crops in progress generally. Cholera and fever in parts of fourteen, cattle-disease in parts of eleven, and small-pox in parts of three districts.

Bengal.—No rain during the week; cold weather setting in. Outside the flooded tracts prospects of late rice harvest are generally very good. In Behar, however, want of some more rain continues to be much felt in places for rice on high lands. Cultivation of *rabi* is in active progress and crops already sown are thriving well. Price of rice has somewhat fallen in almost all districts. Fever prevalent in several localities; public health is on the whole fair.

N. W. Provinces and Oudh.—Weather continues to be seasonable; rain would, however, be beneficial for late rice and *rabi* sowings on high lands; in a few districts *kharif* operations nearly completed, and *rabi* sowings in progress everywhere. Prices are generally steady. Cases of cholera and fever are reported from some districts.

Punjab.—No rain. Fever in the Delhi and Peshawar districts and in the Kabuli taluk of the Rawalpindi district; health elsewhere generally good. *Rabi* operations in progress; *kharif* being harvested. Prices rising in the Lahore districts, falling in the Jullundur and Peshawar districts, and stationary elsewhere.

Central Provinces.—Prospects continue favourable; *kharif* harvest and *rabi* sowings in progress. Fever in a few districts. Prices steady.

British Burmah.—Cholera severe in one district, slight in four districts, elsewhere public health good; cattle-disease slight in seven districts, elsewhere health of cattle good. Crop prospects good, except in Promo and Thayetmyo, where the rainfall has not been sufficient.

Assam.—Weather seasonable; mornings foggy. Public health good; cattle-disease disappearing. Sowing of mustard and winter crop commenced; prospects of crops good, except the *sahi* which has been attacked by insects in different taluks. Common rice '3 seers 14 3/5 chittacks per rupee. Tea is doing well for the season of the year.

Mysore and Coorg.—*Ragi* crop is being harvested throughout the State, except in the Bangalore district, where it is reported to be nearly ready for reaping; standing crops in good condition. Season prospects and public health favourable. Drinking-water and pasturage available. Cattle in good condition; murrain decreasing in the Malnad district. Prices have again slightly fallen.

Berar and Hyderabad.—Weather clear. Cotton-picking progressing; *kharif* crops in good condition; *rabi* sowings continue. Wheat 22 and *juari* 28 seers per rupee in Amraoti. *Rabi* crops are in a healthy condition in Hyderabad; *kharif* crops are ripe and fit for harvesting; *rabi* sowings commenced. General health fair, except in Patlur taluka, where fever prevails. Prices in Hyderabad—wheat 13, coarse rice 12½, white *juari* 19½, yellow *juari* 31½, and *tir* 15½ seers per current stock rupee.

Central India States.—Health and prospects good. Weather seasonable; hot and dry in Satna. Cholera in Rewa—37 cases, 21 deaths. Opium sowings continue in Nimnuch, where water in wells low. Opium sowings commenced in Agar. *Rabi* sowings in full progress in Maunpore, where malarious fever in some places. Prices stationary.

Uttar Pradesh.—Fever increasing in Abu. Tanks, wells, and health good. *Rabi* sowings commenced. Weather dry; cool at nights. Health much improved in Marwar, where crops suffered much from want of rain and prices tending to rise. *Kharif* extremely poor. Rain insufficient for *rabi* sowings in Kherwara where prices rising. Wheat, mung and gram cheaper in Fortabgurh. Fever prevalent in Haroti. Cholera disappeared at Pachpahar. Tanks and wells drying in Kerwaji, where fever prevalent. *Kharif* crops injured from want of rain.

Nepal.—Weather cold and clear. Rice nearly all cut. Crops excellent.

Letters to the Editor.

HYBRIDIZATION OF WHEAT.

TO THE EDITOR.

SIR.—The best experiments on the hybridization of wheat and other cereals that I saw (nearly ten years ago) were at Haddington in East Lothian by Mr. Patrick Sherrieff. The results of these wonderful and successful experiments were embodied in a book entitled, "Improvement of the cereals and an Essay on wheat-fy," by Patrick Sherrieff, William Blackwood and Sons, 1873, and published by subscription by the Farmers of East Lothian and Mid-Lothian. If your distinguished correspondent cannot get this book elsewhere (of which a limited number was published for the subscribers themselves), I shall be glad to lend him the copy in my possession.

S. DATTA,

Settlement Officer, Mohurbhunj.

November 7, 1885.

NOTE.—Perhaps Colonel Ommamney will communicate with Mr. Datta direct :—ED.

WOULD-BE TEA-PLANTERS.

TO THE EDITOR,

SIR.—A "Would-be Planter" may not be displeased if the replies to his inquiry come from a tea-planter, instead of from an amateur in tea.

1. The best climates for tea cultivation are those of Assam, Cachar, Darjeeling, and Western Doorgs. Other climates with rainfall so well distributed over 9 months (from March to November) will do equally well.

2. The best manures for tea are (1) human excrements, (2) oil-cakes, (3) cow-dung, goat-dung, &c., (4) wood ashes, (5) above all, a good cultivation which brings out the fertilising power of a virgin soil.

3. Many proprietors live on their gardens, which as a rule pay best. The mortality of European residents does not show that tea gardens are worse than many municipalities. But gardens newly opened should be avoided, and those who cannot manage with only one or two pegs of whisky per diem had better not live on a tea garden.

4. Elevation is a matter of very little importance. The teas of the Bishnath Company have lately sold as well as those of the Dooteriah Co. (Darjeeling.) Tea-planters are inclined to believe that a higher elevation gives a flavour at the sacrifice of strength. On the whole, there is not much variation in the auction room. If Darjeeling teas fetch a better price than Assam teas, it is because the Darjeeling planters as a body understand manufacturing better than the Assam planters.

5. "What labour would be necessary?" This question cannot be answered so easily. With machinery, 1 to 1½ coolies per acre, and without machinery, 1½ to 2 coolies per acre may do. Some gardens yield 2 maunds of tea per acre, while others yield 9 maunds. The difference in the labour sheets will consequently be great.

6. Tea gardening is not a speculation now. With a sufficient capital and a good knowledge of gardening and manufacture, tea will pay—perhaps, better than any other business. But those who regard it as a speculation had better not trouble their heads about tea.

7. The would-be planters may consult Col. Money and Mr. Watson's Prize Essays, and Mr. Wyman's Tea Cyclopaedia. Better still, they should spend a year on a tea garden before venturing into tea.

S. DATTA.

FOOT-AND-MOUTH DISEASE.

TO THE EDITOR.

SIR,—I have read with much interest the letter of "An Agriculturist," which appeared in your issue of the 24th ultimo, also your own remarks on the subject. In the letter in question your correspondent, in a way, asked your able correspondent, Dr. Bonavia of Stawish, for information, but as the able Doctor is still silent, I venture to offer a few remarks on the subject. Though I am not a professional doctor, I have given a good deal of attention to the treatment of cattle disease; and from my own experience I can say that mouth and foot disease is spontaneously developed in moist, hot climates when cattle are closely herded together: it is also liable to be generated in a mela (fair) and also in a crowded ship, or a long voyage, as Colonel Davies remarks. It also makes its appearance when the early rains set in after a prolonged hot season, when the cattle eat voraciously of the young, rank grass. The blood thus becomes heated from improper food, and also from insufficiency of pure air and water. It is therefore evident that the disease originates first in the digestive organs; and when the blood thus becomes affected, a kind of microscopic entozoa are generated about the corona and clefts of the hoofs. At first these appear to cause irritation, like itch or mange, and in this state the animal, thus affected, seeks relief by licking its hoofs. In this way the disease is communicated to the mouth and tongue, and then ends in sores, when the animals cannot eat anything. Meanwhile the disease makes rapid progress in the feet, and eventually the hoofs come off and death ensues. I think that the other symptoms described by some persons refer to an exaggerated form of the disease. The remedy is to kill only the parasitic animalcule which cause the disease, and for this purpose I give freely bamboo and fig leaves internally. I have treated many cases with success, even in several cases when the hoofs were becoming detached from the feet. If prompt measures are taken at an early stage, the animal does not lose much in condition. Three or four days generally suffice to root out the germs of the disease.

HEM CHANDRA DUTTA.

Calcutta, November 11, 1885.

Editorial Notes.

There is a prospect of Travancore soon being added to the tea-growing districts of Southern India, as the tea plant has been found to grow very well there.

The Times of India objects to the semi-official visit of Mr. Ribbentrop, the head of the Bengal Forest Department, to the Western Presidency, where he has gone apparently to study the forest flora of the place.

We learn that some wine has been made from wild grapes grown by Mr. Barnes on the hill slopes of his Vergomont Estate near Naini Tal, which is said to have a very pleasant flavour. Some samples, which were sent to the Punjab, are said to have been highly commended.

THE Bombay Presidency scored largely at the Antwerp Exhibition. Elsewhere we publish a list of the awards made to Indian Exhibitors. We have no doubt that this will have a very salutary effect upon Indian manufacturers, specially on those who have learnt trades in Jails. This is particularly noticeable in the carpets and tapestry class.

It is said to be now almost certain that the tea crop for the current season will fall short of the original estimates by at least two million pounds. After allowing about two million pounds for exports to the Colonies and America, and one million five hundred thousand pounds for home consumption, the quantity available for shipment to Great Britain is not expected to exceed sixty-three and a-half million pounds.

It is stated that at the bottom of the Raith Colliery shaft in Fifeshire, which is eighty fathoms deep, and where horses are largely employed, mushrooms grow to an enormous size. They

have been partaken of cooked and made into ketchup, and suggest the idea that mushroom-growing on a large and profitable scale may be very successfully adopted "down in the coal-mines." This edible fungus is found in perfection all the year round. In France the mushroom is cultivated in caves which may not inaptly be likened to mines, such is their depth and extent.

A LITTLE time back we had occasion to refer to the intention of the Madras Government to have Cinchona febrifuge manufactured there, under a process different to that adopted at Calcutta. We note that the Director of Cinchona Plantations, Nilgiris, has intimated that this febrifuge has been bottled off by the Medical Store Department in Madras, and is now ready for despatch to the provinces; and has requested that it should be sent out at once, with a request to the various gentlemen to whom it is forwarded to report upon its merits as soon as they conveniently can.

"A NATIVE THINKER," writing to a Madras paper, says:—

It strikes me that Travancore is a country where paper manufacture has good prospects for the following reasons:—

It is a maritime province, highly favourable for importing and exporting, and labour is cheap. There is plenty of water-power available for machinery. Clean white rags may be had, inasmuch as the population of both sexes wear white cotton cloths exclusively. Fibres of various sorts in the shape of materials for the manufacture are also to be had. If the manufacture is to succeed anywhere, it must succeed in that Native State. The Native Government is likely to afford reasonable encouragement to industrial enterprise.

We understand that the Agricultural Department at Melbourne is about to carry out an experiment on a large scale with ensilage at the Dookie experimental farm. For this purpose a silo is in course of construction 33 feet long, 18 feet wide, and 10 feet deep, built up with 9-inch walls from the bottom. It is to be divided into two compartments by a wall running through the centre so as to enable different crops to be tried. The roof is to be of corrugated iron, and there are to be two large folding doors at each end of the building for putting in and taking out the silage. It is intended that, should the building not prove a success as a silo, it is to be so constructed as to be convertible into a dormitory for the farm students.

According to the reports of Indigo brokers, the arrivals up to the present consist entirely of produce from the North-West Provinces and Oudh, of which about 50 chests of Oudhs have been sold privately at an advance of about Rs. 50 on last year's average prices. European indigo appears to be still kept back from the market, and the sales will probably not begin for nearly another fortnight. The outturn of European factories in the North-West will, it is expected, eventually turn out nearer three than four thousand maunds. The boiling masters from the Bengal factories promise that the quality of the crop will be decidedly better than the average, whilst those from Trihoot and Chumparun are rather better than last year, and equal to the standard, but those from Chupra are said to be inferior, wanting soundness in paste and colour.

A CURIOUS case of foot-and-mouth disease having been communicated to a Veterinary Surgeon, referred to by the *British Medical Journal*, which says:—

A case is related in a German journal of veterinary medicine where a veterinary surgeon, two days after declaring a locality to be infected with the foot-and-mouth disease, having to travel in a violent east wind, employed a handkerchief to protect his mouth which he had had in use while he was examining the beasts. The next day he was seized with a violent head ache and pains in the limbs. On the second day there was fever, and a feeling of irritation in the hands and feet. The third day the fever abated, but there appeared on the tongue, lips, mouth, and edge of the nose, an eruption of an aphthous character which lasted eight days.

We noticed a short time back the deputation of Dr. King, of the Geological Department, to report on the probability of obtaining water by means of artesian wells in the neighbourhood of Vizagapatam. We now learn that he has expressed an opinion that there is very little chance of this ever being successful in that district. But Dr. King has made an excursion to Gallikona, where he is said to have made some important discoveries as to the mineral wealth of the district, and a report on the subject is to be published after his return to Calcutta. The existence of plumbago in large quantities is pretty well established, as it is commonly used by the local potters for glazing earthenware. Some traces of gold are also said to have been discovered within a mile of the cantonment; but Dr. King's report must be awaited for full particulars.

The *Gazette of India* of last Saturday published the forms of application for the use of private exhibitors, received from the Royal Commissioners for the Colonial and Indian Exhibition, 1886. The Royal Commission invite applications for space in the Indian section from *bona-fide* merchants and manufacturers having places of business in India; but applications from importers or agents will not be entertained. Applications will also be received from persons desirous of exhibiting oil-paintings, water colours, and drawings of Indian subjects by artists and amateurs resident in India, the Commissioners defraying the cost of packing and freight from Bombay, subject to conditions set forth. A special invitation is issued for the exhibition of samples of tea, coffee, and cocoa from *bona-fide* planters and manufacturers, having places of business in India or the Colonies.

..

The ludicrous mistakes sometimes made by official bodies and Government officers in India, in the classification of animals and trade and agricultural products, have occasionally been noticed by us; but the following, which we take from a contemporary, is something quite out of the common.—

The hare is an unfortunate animal. In the authorised version, he is unjustly accused of chewing his end. In a late schedule sent up by one of the Central Provinces Municipalities he is classed with partridges, peacocks, and quails as a game-bird. It is to be feared that Mr. A. O. Hume has omitted this *rara avis* from his collection. In the same schedule under "Animals for slaughter" appear bullocks, goats, sheep, fowls, and eggs. In a municipality where poor harmless eggs are slaughtered, and where the hare swars aloft among the fowls of the air, the premature appearance of thread and wool as "textile fabrics" may be passed over as an ordinary occurrence.

..

"Paper and the industries connected with it," formed the subject of an interesting address read by M. de Bontarel before a meeting of the Académie des Sciences recently. Some remarkable statistics were quoted by M. Bontarel as to the rapid increase in the quantity of pens, paper, pencils, &c., which are manufactured in Europe and the United States alone. He said that the manufacture of paper alone, which at the beginning of the century was practically all in the United States, now amounts to 500,000 tons per annum, and that it is just double this figure in Europe, the value of straw, rags, and other materials used in the manufacture of the paper being about £20,000,000. He estimated the value of these 1,500,000 tons of paper, when manufactured, at £40,000,000; the note-paper being calculated at 120,000 tons, worth £6,400,000. M. de Bontarel estimated the value of the steel pens manufactured annually at £800,000, while the number of heliotype plates may be estimated at 3,000,000—30 Paris houses alone turning out 900,000. He mentioned the number of lead pencils made every year, and though some of his figures can only be conjectured, they no doubt represent very fairly the enormous capital employed in these industries.

..

A letter, dated 28th August 1885, has been addressed by the Principal of the Royal Agricultural College, Cirencester, to the Secretaries to the Lieutenant-Governors of Bengal and the North-Western Provinces and Oudh, and is published in the *Gazette of India*, to the effect that the Governing Body have passed a

Resolution establishing an entrance fee of five pounds, to be paid by all out-students admitted to the College, from and after the Winter Session beginning October 8th of this year. He therefore begs the favour of this fact being taken into consideration in the terms of the contracts with all future scholars. In making this communication, the Principal takes the opportunity of explaining that hitherto the out-students have not contributed to their fees towards the maintenance of the buildings of the College. Their fees have been solely in regard of the instruction. The number of out-students, however, has in the last few years increased so considerably that, in order to meet a want very strongly felt, the Governing Body are now building a commodious out-students' common room with lavatory and locker-room attached, and it is in consideration of this large outlay and of the circumstances generally that the resolution mentioned has been passed. The comfort and convenience of the out-students and their opportunities for study also will be, he has no doubt, materially enhanced thereby.

With reference to his report on the state of the season in Anantapure during the week ending the 25th July last, the Collector of Anantapure was requested to give the botanical name of the plant or tree called "Gadara," the leaves of which were stated to have been used as an essential article of food by the poorer laborers in three villages of Pennakonda, where there was a scarcity of food; and also, if possible, to send specimens of the leaves, flowers, and twigs of the same. His reply was that the plant, which is also known as "Devadaru," was said to be *Sethia Indica*, and the point being referred to Mr. Lawson, the Director of Cinchona Plantations, he identified the specimens sent to him as belonging to the *Erythroxylon Monogynum*, or its synonym, *Sethia Indica*. We believe that this point was noticed some years ago during the last Madras famine; and Dr. Bidie refers to the subject in his little pamphlet on Coca. The enquiry is worth pursuing a little further, with the object of determining whether the peculiar qualities belonging to the Coca, of staving off hunger and fatigue, are also present in the *Sethia Indica*. A chemical analysis would settle the question, we think. In connection with this subject, we print elsewhere the correspondence which has passed between the Government of India and the Secretary of State for India. The letter from Surgeon-General E. Balfour is very interesting, and contains much information.

..

One of our American exchanges has the following regarding the present season's wheat crops of the United States:—

The Department of Agriculture's September report based on reports to Sept. 1, was given to the press on the 10th instant. As we anticipated would be the case, it makes a still further reduction in its estimates of the wheat crop, and prepares the way for a further coming down by saying "if the injuries reported in the stack should prove to be greater than is at present apparent a few millions of reduction might still accrue." Its present estimates are of winter wheat 217,000,000 bushels, and of spring 134,000,000, a total of 351,000,000 in place of 265,000,000, which was its July estimate. On the spring wheat it admits a loss from the August estimates of 3 points in Wisconsin, 5 in Minnesota, 4 in Dakota, 7 in Iowa, an average of less than five per cent, when it is well known that throughout these States, with Nebraska added, and which constitute the principal spring wheat-producing area of the country, the loss from blight, rust, storms, and insects after August 1 was not less than from 20 to 25 per cent in quantity with an equal loss in quality. The department's estimates on the wheat crop are still in our opinion 33,000,000 bushels too high. The general condition of the corn crop is placed at 95 against 96 in August, and 94 at the same time last year. It says "frosts have done but little damage, and will be capable of little. The prospect is still favorable for a crop slightly above the average." The cotton crop suffered in August from drought and hot weather, worms, &c., and there has been a decline from the August condition in every state. The average for September is '87 against 96½ in August and 82 in September of last year.

..

Those who are very much troubled with grasshoppers, will do well to note the following remedy which has been used with complete success by Professor Coquillett of the U. S. Department of Agriculture:—

"It consists of a mash composed of bran, arsenic, sugar and water, the proportions being one part of sugar one and one-half parts of

arsenic and four parts of bran, to which is added a sufficient quantity of water to make a wet mash. A common washtub of this mash is sufficient for about five acres of grape vines. Fill the washtub about three fourths full of bran, add six pounds of arsenic, and mix it thoroughly with the bran; put about four pounds coarse brown sugar in a pail, fill the pail with water, and stir until the sugar is dissolved. Then pour this water into the bran and arsenic, and again fill the pail with water and proceed as before until all the sugar in the pail has been dissolved and added to the bran. Now stir the latter thoroughly and add as much water as necessary to thoroughly saturate the mixture, and it is ready for use. Throw about a tablespoonful of this mixture under each vine infested with grasshoppers; and in a short time the latter will leave the vine and collect upon the bran and soon commence feeding upon it. Those which are upon the ground six or eight feet from the bran will soon find their way to it, apparently guided by their sense of smell, as those to the leeward of the bran have been observed to come to it from a greater distance than those which were on the side of the bran from which the wind was blowing. After eating as much of the bran as they desire, the grasshoppers usually crawl off, and many hide themselves beneath weeds, clods of earth, etc., and in a few hours will be found to be dead. This mixture costs from 25 to 40 cents per acre of vineyard, including labour of mixing and applying it. In orchards the cost will be considerably less than this. One man can apply it to eight or ten acres of vineyard in a day."

A REQUEST of a somewhat novel character has been preferred by the lessees of the land at present being worked by the Illithorai and Karteri Gold Mining Company (Limited.) It appears that Mr. G. N. Groves, of Coonoor, and Major J. Johnstone had obtained gold-mining leases of certain lands in 1882 and 1883 respectively, and have assigned their interests under their leases to the Illithorai Company by virtue of two indentures. Messrs. Stanes & Co., the bankers and secretaries of the Company, have requested the Government to permit them to retain these lands on putta tenure at eight annas an acre, paying additional assessment for mining. The Company have agreed to pay Mr. Groves Rs. 20,000 in fully paid up shares, plus Rs. 880 in cash for the transfer, while in the case of Major Johnstone, the consideration is 38 shares of Rs. 100 each and no cash. The Collector of the Nilgiris is of opinion that the success of the enterprise, so far as the Gold-Mining Company is concerned, is uncertain, and has referred the matter for the orders of Government as to the question whether some encouragement should not be given as a special case; as the present rent, Rs. 810 annually, is felt to be burdensome. He has accordingly recommended that the land may be granted on putta at Rs. 2 per acre, subject to the additional assessment on the extent taken up for gold-mining, which in the present case will be 24.16 acres in Coonoor. The Board of Revenue are of opinion that the Illithorai and Karteri Gold-mining Company (Limited) may be allowed to relinquish the leases with effect from 1st January 1885, on payment of all arrears of rent up to that date, and to take a fresh lease on the usual conditions of the 24.16 acres of land required for mining purposes. The Board do not consider that any of the lands should be granted on putta, and if the Company desires to obtain them on permanent tenure, it should purchase them under the waste land rules. This has been accepted by the Government of Madras. A standing order will shortly be issued by the Board of Revenue, embodying all the orders of Government on the subject of mineral workings.

THE reports on the state of the season and prospects of the crops for the week ending 4th November, 1885, are as follows:—Rain continues to fall in the Madras Presidency, where the prospects are now fair. In Bellary and Anantapore the crops have been much improved by the recent rain. Rain has also fallen in the Mysore State, where the standing crops are in good condition, and the rabi harvest is in general progress. Murrain is decreasing in the Malnad district, and elsewhere the cattle are in good condition. In the Bombay Presidency slight rain is reported from places in four districts. In Khandesh more rain is urgently required for the rabi crops. Reaping of kharif and sowing of rabi crops are in progress generally. No rain is reported from the Berars and Hyderabad. In the former the prospects of the kharif are good

and rabi sowings have commenced, but in Hyderabad fears are entertained of damage to the standing crops, and rabi sowings have been postponed for want of rain. In Central India agricultural prospects continue favourable. In Rajpootana the crops are suffering in many places for want of rain. Rabi sowings have commenced in a few States. In the Central Provinces prospects continue favourable, and the kharif harvest and rabi sowings are in progress. In the Punjab the kharif is being harvested, and rabi sowings have commenced. Prospects are generally good. Seasonable weather prevails in the North-Western Provinces and Oudh, but the crops require more rain on highlands. The kharif harvest has been nearly completed, and rabi sowings are in general progress. No rain fell in Bengal during the week under report, and the cold weather is reported to be setting in. Except in flooded tracts, the prospects of the late rice harvest are generally very good. In some places in Behar the want of rain is a serious defect. Rabi cultivation is in active progress, and the crops are in promise well. In Assam prospects continue good. In British Burmah the crops promise well, except in Prome and Thayetmyo, where the rainfall has been insufficient. Fever is more or less prevalent in most provinces, otherwise the public health is fair. In Bengal the price of rice has fallen in almost all districts; and in Mysore and Coorg prices continue to fall. Elsewhere they are generally steady, except in the Punjab, where they are fluctuating, and in Rajpootana, where they are rising in some places.

AN American paper of some authority, writing on the inferior quality of American wheat says:

While it is an admitted fact that our wheat crop is this season immensely short in quantity from that of last year, it is not so generally understood, we think, that there is a large additional loss by reason of the comparative inferiority in the weight and flouring qualities of the grain in a large number of States. In quantity as well as quality, probably the States of West Virginia, Tennessee, Kentucky, Kansas, Illinois, and Missouri are the greatest sufferers. In Kansas the result of the harvest is most deplorable, reliable advices reporting the average weight of the wheat over wide areas as not over 45 lbs. to the measured bushel. Such wheat is scarcely fit to make into flour, and at any rate would require a very unusual quantity to make a barrel of it. About $\frac{1}{2}$ to $\frac{2}{3}$ bushels of 60 lbs. each of good plump No. 2 wheat is about what is generally used in our improved mills to turn out an excellent barrel of flour, but of such 'chicken feed' or 'stump tail' wheat as Kansas is reported to have gathered this season, it would very likely take 6 bushels or more to make a poor barrel of flour. The reports from the other States mentioned are not so bad, but they are poor enough to be very discouraging. Regarding the spring wheat crop, the accounts have for several weeks past been coming in poorer and poorer, both in respect to acreable yield and quality. Many fields are not thrashing out more than two-thirds to three-fourths the quantity anticipated, and the weight of much of the grain is very considerably less than the crop of last year. The more backward fields in Minnesota and Dakota were more or less injured by intense heat when the grain was in the milk, the temperature rising on several days to 118 deg. to 120 deg. Of course such intense heat at that critical time more or less shrivelled the berry, and prevented its subsequent growth and development. It is impossible, of course, to form any tangible estimate of the injury the crop as a whole has sustained in its quality from the adverse elements to which in numerous States it was subjected; but in average weight per bushel and flouring capacity, as compared with the crop of last year, the sum total undoubtedly forms a very serious item, amounting to many millions of bushels, and is a loss that is to be taken into account in estimating the result of the harvest just as much as the shortage of acreable yield in measured bushels.

THE applicability of Rule 7, framed under section 26 of the Forest Act, has given rise to much discussion. It was not many months ago that we noticed an amendment of this rule. It has again come up, as the Madras Board of Revenue fear that some misapprehension may possibly exist regarding the scope of the Government Order issued in July last. They therefore think it advisable to explain that it is only intended to apply to those cases where it is contemplated to form reserves of reserved lands; and that in all such cases, prior to any proposals of such a kind being submitted to the Board, it is the intention of Government that the prescriptive rights of the villagers of the villages in which the

proposed reserved lands may be situated, should be first of all carefully investigated and reasonable areas for the exercise of those rights be set aside before the reservation of the rest of the land proposed to be reserved is recommended to the Board. The Government of Madras, however, consider that the Board of Revenue are mistaken in supposing that the order of July 1883, is intended to apply only to those cases where it is contemplated to constitute "reserve lands." Under rule 10 the 'trees and timber' of unoccupied *unreserved* lands are vested in the Forest Department; consequently the application of rule 7 is necessary, even in villages where no "reserved lands" are proposed, for the protection of prescriptive privileges. Further, that the procedure prescribed by the Board seems suitable enough as a preliminary to reservations under rule 7. The Government consider that the inquiry will really be a kind of petty forest settlement, and it is right that it should be held by the Divisional Officer, the District Forest Officer being present, if necessary, to safeguard the interests of the State; but that it is going too far to require an inquiry of this description in all cases where it is proposed to constitute "reserved lands." There is no necessary connection between rule 7 and reserved lands, and the two things should be dealt with separately. Tracts set apart as reserved lands can always be thrown open again, should it appear to be necessary to do so for the purposes of rule 7 or for other reasons. And, lastly, the Government of Madras observe that the Board's Proceedings, of June 1883, which should be read as modified by the order of July 1883, related only to fuel and fodder reserves, the place of which will, to a great extent, be supplied by reserves under rule 7 and reserved lands. The Board is therefore to again impress upon all Collectors the great importance attached by Government to the speedy carrying out of rule 7.

.

A CORRESPONDENT sends the following regarding the Rohtuk Horse Show to a contemporary:—

This Horse Show is of recent establishment, and of minor importance. Rohtak, though the head-quarters of a district, is one of those semi-civil stations which no one visits who is not obliged to do so in the course of duty, and from which those, to whose lot appointments there may fall, lose no time in availing themselves of the first chance of a change of residence. It is a district in which there is but little waste land; it is largely cultivated, and "runs" for young stock are pretty well out of the question. The show was instituted some four or five years ago, with a view to stimulating horse-breeding in the district by the offer of prizes for successful exhibitors, and by affording breeders a market for the disposal of their young stock. As a market for remounts, it has never attracted more than one or two casual purchasers; and this year, though purchasers were present, no remounts were forthcoming. The early bird gets the worm, and as representatives of various regiments have been steadily buying in the district for the last three months, the pick of the local produce has mostly been disposed of. A little over 100 remounts have been purchased in the district since about last August. This no doubt affected the supply brought in to the Show for sale to a certain extent; but the amount given in prizes only amounts to Rs. 350; and though, under other circumstances, perhaps 20 to 30 remounts might have been procurable, the chances are that the remainder would not have come in here, but gone down to the bigger fair at Balesar. In fact, it seems quite an open question whether the site of this show might not, with advantage, be changed (say) to Delhi, and there combined with a show for cattle. Delhi would take a much larger area and catch, moreover, all the "strings" going down country; would be much more get-at-able for both exhibitors and purchasers, and should attract them in greater numbers than now patronises Rohtak. As far as this year's show is concerned, the exhibition of breed stock was poor in quality, and very limited in numbers. As a market there were certainly above half-a-dozen animals in the place fit for remounts, two of which were purchased by the Remount Committee: the remainder presumably holding out for extravagant prices, which the owners hope to get elsewhere. The cattle and donkey shows are held at other places in the district, and it seems a pity they cannot all be combined. There was also the usual ploughing contests, the exhibition of antediluvian agricultural implements, which, however, no doubt answer all the requirements of the Jai cultivator—and that was about all.

The Principal of the Agricultural College, and the acting Director of Agriculture, Madras, do not seem to agree as to the precise nature, extent, scope and control of the "annexe" to the College. Mr. Robertson, the Principal, gives it as his opinion that, "in the interests of the College farm," he should have control over certain land which is to be included in the 'annexe'; and further, that as he proposes giving considerable attention to dairy farming on the College farm, the land might be set apart for grazing the cattle, the whole being laid down in grass. To this the Director demurs; as this in plain language means that the Principal of the Agricultural College proposes to carry on the Saidapet Farm *mutatis nominibus*, and to convert it from one for 'experimental' cultivation to one for experimental dairy-farming; and adds that this is not the intention of Government. He further "objects" to having the Veterinary hospital hemmed in and surrounded by land in Mr. Robertson's charge, and goes on to say that "there were differences when the whole farm was in the hands of one and the same department, and the probability, now that portions of it will be under the control of two separate departments, is, that these will recur." This is unfortunate; as in a matter of public interest there ought not to be such differences. As far as we can see, Mr. Robertson has made out a strong case in favour of his proposal; for why should he not have control over ground attached to the College for instruction in dairy farming? And we fail to see anything objectionable in having the Veterinary hospital surrounded by land in Mr. Robertson's charge. We suspect there is some friction between Mr. Robertson and the Agricultural Department, which is clearly discernible in Mr. Price's concluding paragraph, which says:—"As for the exceptions which Mr. Robertson formerly raised to this plan, I do not think them worthy of discussion." The plan referred to is, the possibility of Government determining to use a considerable portion of the land in dispute for the erection of a reformatory. The Board of Revenue consider that the annexe to the Agricultural College should be strictly limited to the area of about 40 acres included within the limits marked, and that the Principal should have no interest in, or control over, any other part of the farm. And that his proposal to take up dairy-farming should be at once disallowed. Mr. Price's idea that the reformatory (if one is to be built) should be at the farm is one that strongly commends itself to the Board, with a view to the boys in the reformatory being taught agriculture on the experimental farm by Mr. Robertson, and being employed by him as gardeners or labourers on the farm. The Government of Madras have accepted the proposals of the Director and the Board as to what shall be the extent and limits of the farm-annexe to be attached to the School of Agriculture, and have decided that the precise scope of the operations to be conducted thereon will be determined in the Educational Department. They note, however, that the expression "experimental farm" is inaccurate, the annexe being intended for practical *demonstrations* only, and not for experiments.

.

"WARAS" is the name of an Arabian drug or dye stuff, the plant producing which has been identified as occurring in Southern India. This has formed the subject of a correspondence between the Madras Government and the Secretary of State for India, with the object of ascertaining its value as a dye. An experiment was accordingly carried out by Mr. Thomas Wardle, the well-known silk dyer of Leek, Staffordshire, in communication with Mr. Thimelton Dyer. The latter in forwarding Mr. Wardle's report to the India Office observes that the illustrative specimens so admirably prepared by Mr. Wardle should, in Sir Joseph Hooker's opinion, be sent to India to be deposited in the Central Museum, Madras. Further, that Sir J. Hooker thinks that, the China silk dyed with "Waras" by Mr. Wardle, show great delicacy of tint; and he does not see why the dye, the use of which in India from an indigenous source appears to have been previously known, should not have at least a local value. Mr. Wardle's report, dated 14th July, 1885, addressed to Mr. Thimelton Dyer, runs as follows:—

In reply to your letter, dated 27th February, asking me to examine the sample of "Waras" which accompanied it with regard to the

properties as a dye, I beg to state that I have so examined it, and I send you herewith a few specimens of mulberry silk tassar silk and wool which I have dyed with it. This substance contains only a small amount of coloring matter compared with the vegetable yellow dye of commerce, and no colors can be obtained from it which will bear comparison in depth and richness with those produced from Kamila or Kapila, which, it is stated in the Kew Report for 1880, it is used as a substitute, and which is certainly a very much more valuable dye-stuff. As far as my observations have gone, Waras is inferior to Kamila in permanence, as regards the action of light. Below is a specimen of the dyed fabric which accompanied your letter of 27th February, which has been exposed to light for three months, compared with a specimen which has not been so exposed. The color produced by Waras is easily turned brown by alkaline solutions, whilst Kamila is only slightly reddened. Both dyes, however, resist the action of acids very well. It probably would be well, if possible, to get another and larger sample of Waras and make further experiments, especially as Professor Lawson intimates that the sample sent has been damaged owing to the excessive wetness of the season.

I corroborate the statement of Professor Lawson that Waras is suitable for a dye for silk rather than for wool, and that it is useless as a dye for cotton. I have tried it on cotton with most of my mordants, as well as without mordant, and the result is only a very pale shade of yellow. I send you four cards containing trials made with the dye stuff:—

No. 1 contains nine specimens of Corah silk (mulberry silk) cloth dyed with Waras—

3 specimens, R process.	} methods of application of my own.
3 " " A " "	
3 " " G " "	

No. 2 contains nine specimens of tassar silk dyed with Waras—

3 specimens, R process.	} methods of application of my own.
3 " " A " "	
3 " " G " "	

No. 3 contains nine specimens of wool dyed with Waras—

3 specimens, R process.	} methods of application of my own.
3 " " A " "	
2 " " I " "	
1 " " G " "	

No. 4 contains seven specimens of mulberry silk dyed with Waras and Waras mixed with other dyes (aniline)—

3 specimens Waras alone.

4 do do, mixed with other dyes (aniline)

Also a specimen of organzine, for comparison, dyed with Kamila or Kapila (*Mallothea Phillipensis*). It has been decided to send another larger sample of the dye for further experiments.

The first annual report of Mr. OZANNE, the Director of Agriculture in Bombay, is very favourably reviewed by the Governor of Bombay, who is of opinion that, considering the short time during which Mr. OZANNE has been in charge of the Agricultural Department, the ground traversed by the report is sufficiently wide, and proves the great interest he has taken in all subjects connected with his department. The principal objects for the establishment of an Agricultural Department namely, to place under skilled, central, and systematic direction desultory, fragmentary, and unsystematic experiments, to maintain a trustworthy record of such experiments and observations, to aid and encourage higher cultivation, to bring the produce in contact with the exporter, and to furnish agricultural facts and statistics, serviceable alike to the Government and the trading community, have been very correctly realised by Mr. OZANNE, who during the short time he has been Director of Agriculture in Bombay, has succeeded in "introducing into the Dharwar district a new staff of revenue inspectors who supervise village accounts as well as collect agricultural statistics." If the system works well in Dharwar, it is intended to extend it gradually to other districts. Among other works which Mr. OZANNE did during the year (1883-84) was the useful note which he wrote on the use of rab. Mr. OZANNE's investigations in this direction confirm the opinion held by the natives, that rab is used expressly for the purpose of roasting the soil, with the view of destroying the germs of vegetation likely to prove destructive to young plants, than for manuring it. On the subject of the working of experimental farms, the Director has made a few remarks, which the Governor of Bombay commends to the notice of the Superintendents of the Experimental Farms at Hyderabad in Sind, and at Bhadgaon in Khandeish. Among the more important directions are that

all experimental plots should be duplicate, and not triplicate. Each series of experiments should comprise an exemplar plot in duplicate which is necessary for the sake of comparison. "Thus if a particular plot is being tested, the exemplar plot will contain the chief crop of the rotation alone and year by year, in order that the effect of the rotation of that crop may be estimated at its true worth." The farm should be divided into a purely experimental and a general portion. The area in the experimental portion, though small at first, should be expanded gradually. As everything depends on the success of the experiments, it is suggested that these, "to be productive of reliable results, should extend over a number of years, and that the regularity of the plots is of the first importance to ensure a proper comparison of the results of one year with that of former years." In connection with this subject, it is said that "a further experiment in the curing of tobacco in Kaira is in contemplation, and the Government of Bombay have consented to bear a large share of the cost for another year." During the year, Mr. OZANNE devoted special attention to the subject of ensilage, important experiments in which were conducted at Kirkee with the assistance of Lieutenant-Colonel CALDECOTT, R.A. The results are considered to be satisfactory, and a hope is expressed that the Commissariat Department and the contractors, seeing the value of it, will soon commence to use it for their cattle.

THE EFFECTS OF TEA-DRINKING.

This is an old subject, and has been so threshed out, that one might have thought there was no phase of the question left untouched. The *pros* and *cons* have been argued from every point of view, and by all sorts and conditions of men. Yet, in the search for fresh topics to descant upon, "an old friend with a new face" has been overhauled. Even the pages of a novel have afforded an esteemed contemporary a theme for a scientific dissertation on the alarming effects of tea-drinking. If by attracting prominent attention to a matter affecting a vast community, it is intended thereby to lessen the evils resulting from an over-indulgence in a beverage which has been aptly termed "the cup that cheers but not inebriates," then we say that it is only right and proper that erring mortals should be set right; but even then we are of opinion that it is well not to draw the bow too long. But let us see what our contemporary, the *Madras Mail*, has to say on the subject. The paragraph that has inspired the article under reference, occurs in the 25th chapter of a novel now appearing in the *Cornhill Magazine*, entitled "Court Royal." The steward of the owner of "Court Royal" is made to address his son, Beavis, as follows, one morning at breakfast:—

"I never take tea with meat. No tea, Beavis; coffee for me; less tannin in it. Can you conceive anything more calculated to give dyspepsia than to immerse meat in a fluid charged with tannin? You convert it at one stroke into leather, and make demands on the gastric juices which it is not qualified to perform. No, tea is poison; give me coffee." * * * "But mind, Beavis, remember what I have said about drinking tea with meat. You deliberately tan your food, and yet you expect to digest it. As well eat sole-leather."

Although our contemporary's comments are somewhat lengthy, it is desirable to quote them *in extenso* for a proper understanding of the line of argument taken. This is what he says:—

To say the least this is disquieting, for although it appears in a work of fiction, it refers to a matter of fact. No one denies that a hot infusion of coffee, or tea, is invigorating, and useful in fatigued states of the system, and preferable generally to alcoholic drinks. The late Dr. Parkes says in his standard work on Hygiene, that "coffee and tea have a stimulative and restorative action on the nervous system, which is perhaps aided by the warmth of the infusion," while the action of the skin which is induced is also useful. This has been the experience of many of our late campaigns. Tea and coffee are equally serviceable, and acceptable in all climates, and if drunk in moderation, they leave no after depression. The active principles of tea and coffee, theine and caffeine are chemically and physiologically identical, but tea contains what coffee does not, namely, tannin, and it is chiefly due to

This constituent of tea that certain evil effects are observed to arise from immoderate tea-drinking. Tannic acid, or tannin (so called "because it is the ingredient which in oak bark is generally employed for the tanning of leather"), besides acting as an astringent, precipitates, or unites with albumen, and in this way forms an insoluble substance with the albuminous matters of food in the stomach. Such matters are thus rendered less soluble and easy of digestion. Tannic acid lessens the secretions of the stomach, and diminishes the solvent powers of the gastric juice. Hence it is inadvisable to take substances containing tannin close to meal times; and experience teaches that tea at heavy meals is not so good as coffee. Tea itself is consequently productive of dyspepsia (especially of flatulent dyspepsia), and a continuation of the habit of drinking large quantities of tea simply aggravates the disease. This form of dyspepsia is probably rife in Russia where the samovar, or tea run, is always on tap, alike in palaces and in hovels. Dr. Richardson in his "Diseases of Modern Life" describes the symptoms which indicate the injurious action of tea. They are severe headaches, constipation, flatulency, muscular feebleness, and "lowness of spirits amounting to hypochondriacal despondency." This lowness of spirits under the influence of tea is very marked in children, and an "extremely nervous, semi-hysterical condition from the action of tea, is all but universal in poverty-stricken districts in England amongst the women who take tea at every meal." Nervous symptoms have been much developed in the richer classes of society, in London and other fashionable centres, since the revival of the custom of tea-drinking in the afternoon, and escape from the wretched feeling which is thus engendered is too often sought by recourse to alcoholic "pick-me-ups."

In fact the inference to be drawn from the foregoing is that like everything else, an undue indulgence in the use of tea, is certain to be followed by injurious effects, calculated in a greater or less degree to derange the assimilative organs of the body. How far these arguments are borne out by ascertained facts, we shall examine further on. The *Madras Mail* goes on to say that—

There is reason, however, to suppose that a large number of people imagine that tea is perfectly innocuous, that the only thing to be guarded against in its use is the avoidance of drinking it in the evening, since it tends to cause wakefulness. Hence, there are among us people who are immoderate drinkers of tea, and confirmed dyspeptics. Dr. Johnson used to drink tea not out of cups, but out of basins, and he was at times the most morose and irritable of men. One cannot be immoderate in anything without having to pay a penalty.

To anybody with comparatively sluggish digestive powers, the imbibing of a copious quantity of any liquid must in the nature of things be deleterious. The digestion and assimilation of food cannot go on properly if one pours bucketful of tea, or even water, down the much enduring Red Lane. Anything that can be proved to hinder digestion, or to cause indigestion should be avoided, no matter how seductive it may have become by long habit and old association. It is practically impossible to do oneself justice, or to take reasonable views of life, while one is a martyr to "the blues." Indigestion, when it becomes habitual, throws a glamour over and tends to embitter and shorten life. The victims of it usually resort to medicine, and forget the need of considering their diet. They obtain temporary relief, but the demon is not exorcised, he is merely taking a little holiday, and he speedily makes his presence felt again. English people now drink nearly five times as much tea as coffee, the proportion being 4.62 lbs. to 0.89 lbs. Forty years ago, or in 1845, they drank but little more tea than coffee, the proportion being 1.59 lbs. to 1.23 lbs. respectively. In this country Europeans (especially the weaker vessels) often drink more tea than is good for them. They take it at *chota hastee*, or immediately upon waking; at breakfast; and in the afternoon; and they hardly ever touch coffee, though it is indigenous to the country. And natives too, when they get the chance, develop a great avidity for tea. It is computed that about three-fourths of the human race drink tea, coffee, chicory, or cocoa.

In a word, beware of the latent property in tea that is capable of converting your interior into the similitude of a tannery. "There is nothing like leather," remarked a philosopher in the trade; but it is just as well not to tan one's food so as to make it as hard of digestion as sole leather.

The foregoing remarks appeared in an issue of our contemporary last month; and we thought, when reading them, that a very important factor had been lost sight of. It is pretty well

known that the nourishing and invigorating properties of tea are due to the presence of theine, which is the active principle and that in preparing the beverage, care should be taken not to allow the leaves to infuse too long, as then tannic acid, which is largely present in tea, is extracted, and this substance it is that acts prejudicially on the digestive organs, by uniting with the albumen contained not only in the milk, but with other albuminous matters of food in the stomach, thus forming a compound bearing an analogous resemblance to leather, which is far from being easily digestible. And when we consider the intemperate use of tea in conjunction with its mistaken preparation as a beverage, it is not surprising that dyspepsia and its attendant evils should be the result. We, however, refrained from referring to the subject, as we considered that probably these simple facts were generally known. In a recent issue of the same paper (*Madras Mail*) a correspondent from the Nilgiris, signing himself "One of Them," replies to the article we have been quoting; and as the facts and arguments advanced by the writer are entirely in accord with our own knowledge of the subject, we reproduce the letter below for the benefit of our readers:—

With reference to an article in your issue of the 23rd instant, about the horrors of a cup of tea, will you kindly allow me, in the interests of the large community of tea planters as well as of the public, to offer a few remarks thereon? If the stomachs of the tea drinkers are destroyed by tannic acid, they may comfort themselves with the reflection that it is entirely their own fault! This may seem a sweeping assertion to make, but I will show that such is really the case. Every one, I suppose, is aware that the nourishing, refreshing property of tea is the theine, and also that the tea leaf yields up the same theine more quickly than the bug-bear tannic acid; consequently the avoidance of the injurious effect of tea is manifestly easily effected. Infuse your tea leaf such length of time as will extract all the beneficial properties of the leaf, but will not extract the tannic acid. There has been a great conflict of opinion amongst authorities as to what length of time is necessary. Some say five minutes and others ten minutes. I can only quote my own experience, however, I am accustomed not only to drink my cup of tea regularly, but also to test teas. Provided the water used be at the boiling point when poured over the leaf, I detect the presence of tannic acid at once, if the tea is not poured out in three minutes' time. What must be the nature of the brew in ten minutes' time! And what in twenty minutes!! And yet there is generally no care observed as to length of infusing tea. Some time ago, at the house of a friend, I drank a cup of tea which was so much better than that generally met with, that I ventured to take the liberty to make enquiries. My hostess replied, "Oh! I always make the tea with my own hands, and would never think of leaving it to servants." The moral is obvious. If, then, tea be infused for exactly three minutes, the resulting fraction of tannic acid present will be so exceedingly insignificant as to be quite inappreciable. Allow me to correct an error in the same article under discussion: coffee does contain tannic acid, but less than half the proportion in tea. Should any nervous reader still feel shy of tea, in spite of the above remarks, let me add, for that same individual's peace of mind, that in hill or mountain grown tea, the percentage of tannic acid decreases in quantity with the increasing elevation at which it was grown, and a correspondingly larger proportion of theine takes its place. This is the reason of hill and mountain grown teas tasting weaker than tea grown at low elevations, which latter contains more tannic acid. But unfortunately, the larger the proportion of tannic acid, the more the general public appreciates the same. Until people are better instructed regarding the properties of tea, such must still remain the case. The statements put forth in papers in England are simply ludicrous. For instance, a short time ago the question was moved whether that splendid Mandarin tea which never crossed the boundaries of China, and was of such remarkable strength that two small leaves sufficed to make a cup of tea (I could not be procured for consumption in England). In a recent prospectus of a new tea company in London, the public are warned that four crops of tea are gathered during the year, and that the first crop contains the largest proportion of theine, whilst the last crop scarcely contains any! The finishing touch to this remarkable statement is given in the flourishing certificate of an F. C. S. and F. R. M. S., who duly certifies that the "aroma" of this too wonderful tea is pungent!!

Resume. Never allow tea to soak longer than three minutes, the utmost, five minutes. See that the water is at boiling point before infusing the leaf. Avoid the use of boiled or warmed

milk in tea. Limit the consumption to the average of three cups a day, viz., morning, afternoon, and evening. If these simple directions are observed, there is no fear of tea having any injurious effects, nor of anybody's stomach being turned into a miniature tannery.

MYRABOLANS.

THE development of this industry in India is of comparatively recent date. It is not because it did not exist in an indigenous state in the country, but because, like most other industries, it wanted an impetus given to it, or we should say a demand created. The trees which yield the myrabolans (sometimes erroneously written myrabolama) of commerce belong to the natural order Combretaceae, and are of two varieties, viz., the *Terminalia Chebula* and *Terminalia Belerica*. The entire genus is known as the myrabolan order, and all the species are natives of tropical regions. No less than 12 varieties are to be found in India. The two we have named above, yield the myrabolans of commerce. The bark and leaves of another species (*Terminalia Catappa*) yield a black pigment from which Indian ink is made. A milky juice is said to flow from *Terminalia angustifolia*, which when dried is fragrant, resembling benzoin (hence its synonym, *T. Benzoin*) and is used as a kind of incense in the churches in the Mauritius. The dried milk is sold in the Indian bazaars, and sometimes takes the place of gum-resin. The *Terminalia Catappa* also yields a kernel, very similar in appearance and flavor to the common almond, and is sold in the Calcutta markets under the name of *Jesi badam*. The genus is widely distributed all over India, but is found growing in great luxuriance in the N.-W. Provinces, Bengal, the Central Provinces, and Madras. Any soil that is clayey, or even a sandy loam, suits it.

With the foregoing preface we shall consider what progress the trade in myrabolans has made of late years. In the report in the railway-borne traffic of the Central Provinces for 1894-85, it is stated that during this year, myrabolans were separately registered for the first time. The exports in the previous year were nil, but amounted during 1884-85 to 2,24,193 maunds, valued at Rs. 5,74,495. Of course, they formed part of the export trade in previous years, but the amount must have been inconsiderable, and we suppose they came under some general or miscellaneous head. The trees from which these myrabolans were produced are called in the Central Provinces "harra" and "bahera," and the Director of Agriculture states that they are found growing abundantly in many parts of the provinces, and promise to become a most productive source of forest income. That the export is at present principally derived from the Satpura forests in the Jubbulpore and Nerbudda Divisions, while the Chhattisgarh forests only contribute a quarter of the quantity exported. He adds that the extension of the Chhattisgarh Railway towards Calcutta will bring into the market very great supplies of myrabolans, which are now wasted in the jungles of Raipore, Sumbulpore, and the Native States surrounding them. Attention has recently been called to the great production of this fruit in the Sumbulpore district, and it has been pointed out that large profits would accrue to the Government forest could export trade in myrabolans be established. Bearing this last fact in mind, it would be interesting to learn whether any protective measures have been set on foot in the Central Provinces to preserve the trees yielding this product from wanton destruction, for it must be remembered that the bark and leaves possess astringent properties, and it has been brought to notice in the Madras Presidency that trees are felled wantonly for the sake of the bark, leaves, and fruit.

With reference to the Madras Presidency, we have before us the report of Mr. J. S. Gamble, the Conservator of Forests, northern division, Madras, of March 1885, in which he submitted certain proposals for the conservation of myrabolan trees and the development of the industry generally. His proposals briefly were that all tracts on which the myrabolans, grow including other valuable forest trees, should be placed under the Forest Act, with simple rules for management of definite areas of reserved forest. After the settlement of prelimi-

naries, he recommended the collection of myrabolans departmentally by employing hill-men as collectors, and paying them at a percentage on the market value to be fixed yearly for the season in which they are ripe. So far therefore as Madras is concerned, the myrabolans form a Government monopoly. And although this may not be the best plan for developing the industry, yet it is, for the present at least, the only one whereby the trees can be best protected from destruction and denudation. The *Terminalias* are very common in Bengal, and may be seen planted along roadsides, where they form fine umbrageous trees. We are not aware, however, whether the produce of the trees forms any part of the export trade: we should think not, for we have not seen mention made of them in the usual trade reports. With regard to the N.-W. Provinces, where these trees grow in great luxuriance, we have no information as to the trade in myrabolans; but that it is capable of being developed, there can be little reason to doubt. In the Punjab, only solitary specimens are to be met with here and there, but we should think that in the Western Presidency there must be large forest tracts of *Terminalias*, yielding large quantities of myrabolans. If properly worked, this industry is capable of yielding a very respectable revenue. We have here endeavoured to place before our readers a few facts concerning the myrabolan trade, which promises to assume large proportions at no distant date.

Miscellaneous Items

MR. BURGESS, Archaeologist to the Governments of Bombay and Madras, has just returned to India after an absence of eighteen months. He proceeds to Guzerat to resume his investigations.

ACCORDING to the *Timber World*, the loss to the United States through forest fires is now not less than 300,000,000 dollars a year, a sum equal to the interest on the public debts of all the civilized nations of the world, through the carelessness of boys and hunters. Locomotives should use spark-arresters during the dry season, and underbrush from the woodland ought to be systematically removed.

THE petrified human eyes from Peru, which are mentioned as the latest Transatlantic ornament, seem rather dangerous novelties. Several workmen engaged in cutting and setting the eyeballs have been taken seriously ill, affected, it is believed, by the strong acids and poisons used in embalming the Incas, to whose bodies the eyes belonged. To fit the eyeball for use it is cut into four or five layers, which are well polished. The eye is as soft as an onion, and resembles iridescent glass.

THE prospects of the *kharif* crops in the N.-W.P. are as follows:—Cotton and maize are good, and will yield not less than three-fourths of a full crop; *bajra* and *til* about the average, and pulses rather above it. *Juar* bad, and the late sown, very bad. Rice, early sown, will yield above the average, except the very earliest, which rotted from the August rains. The late sown rice felt the want of rain in October, but is mostly planted in districts where it can be helped by artificial irrigation. In fine, there is little to complain of, and much to be thankful for.

THE experimental installation of the electric light at the Madras Club has now been extended as far as the power of the machines will admit, and embrace the most important rooms in the building. The current is generated by an Edison dynamo-machine, driven at a speed of 1,200 revolutions a minute by one of Marshall and Co.'s engines hired from the Public Works Department for the experiment. There are three "circuits" or pairs of wires, conveying the current from the dynamo-machine to the house, each of which can be turned on or off at will by the attendant in the machine room. The largest of these circuits, which conveys the current to the reading room, bar, dining rooms, and passages is divided into a number of small sections, each consisting of six, nine, or twelve lamps; any one section being extinguishable at will. Again each lamp is fitted with a tap like a gas jet, and may be lit or put out when required. Lamps of sixteen-candle and ten-candle power are used, the latter being suitable for the passages, where much light is not wanted.

MR. HAYALL, the Superintendent of the Madras School of Art, has received instructions to make a tour, in his capacity as "Art Reporter," in the Northern districts of the Presidency, similar to that made by him last year in the South, with the object of reporting upon the art industries of these districts and selecting specimens for exhibition at the local School of Arts. The sum of Rs. 200 has been allotted for the purchase of specimens and Mr. Hayall will start shortly on his tour, Captain Tafnell, the Adjutant of the Madras Volunteer Guards, being his *locum tenens* as on the former occasion.

An addition which has recently made to Bombay local industries claims attention less for its intrinsic interest than as an illustration, of what may be done in the way of supplying the necessities of the country from its own manufacturing resources. A Bombay medical man, who would never have taken to match-making except in order to show his countrymen that they can produce in their midst commodities for which they have hitherto sent to the ends of the earth, has for a long time past patiently expended time, and thought, and money in the endeavour to establish in Bombay a match factory from which matches as good as those which we now import from Sweden, Belgium, and elsewhere in Europe can be turned out. The experiment, we believe, can already be spoken of as a commercial success. For some weeks past Bombay-made matches have been on the market—matches equal in all respects except perhaps neatness and finish—to the Swedish article, and they are sold at a fair profit for fourteen annas a gross or two boxes for a pie. The chemicals are of Indian origin, and the whole process of manufacture, including the making of the boxes, is carried on in the Bombay factory. The wood is the only imported material, but it is cut up here, and it is hoped that a wood equally adaptable for match manufacture with European pine may be found in the Indian forests.

Selections.

THE SOIL OF THE FARM.

BY W. D. BOXTON.

THE intelligent man in buying a farm first satisfies himself as to the quality and capacity of the soil. It is a matter of vital importance to himself and family. From the soil their subsistence must be gained. Here, if he so cast his lot, must be invested the accumulated earnings, the wealth of mind, and strength of body, with which he has been endowed. It is little to be wondered that his first thought is for the soil in which he invests his all, and from which he should receive so much.

While those who are just locating on land can, to a measurable degree, select the soil that they deem best adapted to the branches of farming they wish to pursue, those who are already established upon farms, must learn to make the most of the soils upon which they are placed. It is a very poor soil that does not possess some quality that makes it superior to other soils for certain purposes. If this truth were more generally appreciated among farmers, there would be less dissatisfaction and moving about. The farmer on the light hilly soils of the north eastern states, is prone to sigh for the fertile prairies of the west. He knows that they who till the western lands, can pour the golden wheat down at his very door for a smaller price, that he can profitably produce it. He feels that he cannot successfully compete with them, and in that he is right. But he can do better. He can produce that to which his soil is better adapted, and which his proximity to large markets will make profitable.

In buying land for farming purposes, the purchaser is very likely to select the most fertile, if it be within his reach. Usually his first question will be, "How much wheat will it yield to the acre?" When he has satisfied himself that it is a good wheat soil, he is quite ready to purchase without much further inquiry as to other qualities and conditions. To be sure a good wheat soil will often produce other crops most satisfactorily; but as there are many good wheat soils that are not at all favorable for mixed farming, the wheat-producing power of the soil should not entirely govern one in his estimate of the value of land. The farmer should bear in mind, too, that wheat-growing followed continuously and exclusively, will soon exhaust even the strongest soils. The continued growing of any crop that is not fed out on the farm, must sooner or later impoverish the soil.

Before going further, we will briefly consider the character of the different soils, and the proper treatment of each. As it is not within the scope of this work to go into minute divisions and sub-divisions, only those soils with which the farmer has to practically deal, will be treated upon.

CLAY SOILS.

The clay soil, or soils, deserve, perhaps, first consideration. Clay is found in varying quantities in nearly all soils, while in the clay soils proper it is, of course, the principal constituent. Clay predominates in our strongest and best soils. The pure clay soil is sometimes found, but is not desirable for agriculture. Clay is an excellent ingredient in soils, even in very large quantities, but without the modifying effect of sand and loam it can hardly be handled by ordinary methods of cultivating.

By judicious management a soil that contains large quantities of clay, or what would be called a strong clay soil may be made to produce the very best results. Strong clay soil contains but little vegetable mould. The particles of clay are very fine and compact, and form an almost impervious soil. The addition of water unites these particles still more closely, forming a plastic compound. During a drought, or even in ordinary dry weather, such a soil will bake and crack open in seams and fissures, times two or three inches in width. To remedy this the water must be drawn off as quickly as possible—a work best accomplished by under-draining. Surface or open drainage will partly answer, but is decidedly inferior. Where under drains are used the water sinks down through the soil, leaving little open pores for the entrance of air, and the soil at the same time retaining sufficient moisture for its needs.

Clay is perhaps the most difficult of all soils to work. If cultivated when too wet, it becomes lumpy and hard when dry. If ploughed when very dry a considerable power is needed, and then the work is poorly performed. For this reason, if for no other, clay lands should be thoroughly under-drained that they may be kept in proper condition to work at nearly all seasons.

Clay, more than any other soil, needs the pulverizing action of the frost. In order to give the frost a good chance the ploughing must be done in autumn, that the upturned surface of the furrows may be thoroughly exposed through the winter. Frost is a great disintegrating power. It is inexpensive and works alike for all.

Clay soils should not be rolled or pressed as the already too great tendency to compactness will be increased thereby. If properly handled, the soil will not become so lumpy as to render the use of the roller necessary. Fine toothed harrows and cultivators are prime necessities in handling such soils. Coarse green crops are also highly beneficial when ploughed under on such soils, as they tend to separate the masses of compact earth. Coarse manures of any description act in the same manner. Clays are rich in inorganic elements of plant food, and have a wonderful power of retaining any organic manure applied to them. They also draw heavily from the atmosphere. Clays taken from far below the earth's surface, where it was impossible for them to become fertilized with organic manures when exposed to the air and moisture for a time, have been known to grow and mature heavy crops of vegetation.

A clay soil with a large admixture of loam, or what is commonly known as a clay loam, is much more desirable for agricultural purposes than a strong clay soil. Such a soil is much less compact and consequently more easily worked than the pure or even strong clay. It contains considerable sand and vegetable matter that greatly increases the warmth and dryness. Clay loam is also suited to a greater variety of crops than the strong clay. It should, however, be treated in substantially the same manner as that given above for strong clay soil.—*Farmers' Review.*

LIST OF AWARDS MADE TO EXHIBITORS IN THE BOMBAY SECTION OF THE ANTWERP EXHIBITION.

SECTION I. Group I, Class 4 Printing and Books.—Silver medal to the Government of Bombay (Book Depot) for printing and books.

GROUP I, Class 6, General application of the Art of Drawing and Modelling.—Silver medal to Zoonkar Khan for Delhi paintings. Silver medal to Framjee Pestonjee Bhangara for Poona figures, &c. Bronze medal to Govind Wishwanath Dongri for Poona figures, &c.

GROUP I, Class 8 Musical Instruments.—Bronze medal to the Government of Bombay.

GROUP I, Class 11, Maps and Geographical Apparatus.—Silver medal to the Government of Bombay.

GROUP II, Class 12, Cheap and Fancy Furniture.—Silver medal to Mulchand Bhai Hattening for carved work. Silver medal to Framjee Pestonjee Bhangara. Bronze medal to Santaya Bin Sadhaya for carved work. Bronze medal to Ganpatra Bin Govind Shetti for carved work. Honourable mention to Purshotam Khushal Dhalgar for carved work. Honourable mention, Sorabjee Jamarjee Billimoria for carved furniture. Honourable mention, Jamsetjee Shapurjee for carved furniture. Honourable mention, Moti Kuber for carved furniture. Honourable mention, Jamsetjee Nowrojee for carved furniture.

GROUP II, Class 15, Pottery.—Bronze medal to Government of Bombay. Bronze medal to G. W. Terry, Esq. Honourable mention to H. H. the Gaekwar of Baroda.

GROUP II, Class 16, Carpets, Tapestry, &c.—Gold medal to Supdt. of Yerroda Jall; silver medal ditto Agra do; silver medal ditto Ajmere do; bronze medal ditto Hazaribagh do; bronze medal ditto Bhagalpore do; Honourable mention ditto Hyderabad (Sind) do; ditto Lucknow do; ditto to Donabhy Merwanjee and Co., ditto to H. H. the Nawab of Cambay.

GROUP II, Class 19 Gold and Silver Smiths' Works.—Silver medal to Framjee Pestonjee Bhangara. Honourable mention to the Government of Bombay. Honourable mention to Messrs. Carretjee and Sons of Ahmednuggur. Honourable mention to H. B. Rao of Kutch.

GROUP II, Class 23 Perfumery.—Honourable mention to Messrs. Bana and Co., Nasari. Honourable mention to Sorabjee Jamarjee Billimoria.

GROUP II, Class 24, Leather Work, Fancy Articles, &c.—Silver medal to Government of Bombay for horn articles, &c.

GROUP III, Class 25, Cotton Threads and Fabrics. Bronze medal to the Government of Bombay; ditto ditto R. of Kutch; ditto ditto T. D. Exporance; ditto ditto Zamuck Shaw and Co.; Honourable mention to Dyau Chai Shaw; ditto ditto Bhakur Keshad Shaw and Co.; ditto ditto Kaiser (Sind) Spinning and

Weaving Co. Honourable mention to Anglo-Indian Spinning and Weaving Co. Honourable mention to Great Eastern Spinning and Weaving Co.

GROUP III. Class 26. Threads and Fabrics of Hemp.—Honourable mention to Superintendent of Central Jail, Lucknow.

GROUP III. Class 29. Silk and Silk Fabrics.—Gold medal to Government of Bombay. Silver medal to Sassoon and Alliance Spinning and Weaving Company. Silver medal to Vrijbhukhundaas.

Bronze medal to Mohan Khomchand; ditto to Eknath Khomchand; ditto to Kalyanohand Lalchand; ditto to F. P. Bhangara. Honourable mention to Zoomuck Suaw and Co; ditto Thakur Pershad Shaw and Co.

GROUP III. Class 29. Clothing of both Sexes.—Bronze medal to the Government of Bombay. Honourable mention to H. H. the Nawab of Cambay.

GROUP III. Class 34. Jewellery and Precious Stones. Bronze medal to Framjee Pestonjee Bhangara. Bronze medal to Cursetjee and Sons.

GROUP III. Class 37. Toys.—Silver medal to F. P. Bhangara.

GROUP IV. Class 41. Agricultural Products not used for food.—Gold medal to Chamber of Commerce, Bombay, for raw cottons. Silver medal to Anglo-Indian Spinning Company for raw cottons. Silver medal to Pestonjee Bomanjee Dantia. Honourable mention to Government of Bombay.

GROUP VI. Class 63. Cereals, &c.—Silver medal to Ahmednagar Agricultural Society. Bronze medal to Chamber of Commerce, Bombay.

GROUP VI. Class 68. Condiments and Stimulants.—Silver medal to Framjee Nowrojee; ditto to Rustonjee Bhikajee; bronze medal to Cursetjee and Sons for pickles. Honourable mention to Framjee Nowrojee; ditto to Rustonjee Bhikajee and Co; ditto to Cursetjee & Sons for James.

GROUP IX. Class 79. Bibliography.—Gold medal to Bombay Government.

T. WASHINGTON, Major-General,

By order of his Excellency the Right Honourable the Governor in Council,

J. NUGENT, Secretary to Government.

A PARADISE OF FRUIT.

THE eye of a stranger strolling through the roomy market-places of San Francisco is attracted at once to the fruit stalls laden with all the varied fruits that may be found in the temperate and even warmer latitudes of the world. From early spring to late autumn the same tempting pile in varied forms may be seen, and seen, moreover, with the comforting reflection that the modest sum of five cents (2½d.), the smallest current coin of California, will purchase more of the luscious wares than can be comfortably eaten at a sitting. In this very month will be found the peach in all its many kinds, large and small, cling stone and free; pear of every hue and shape; figs purple and white; golden apricots, plums, apples, strawberries, raspberries, blackberries, currants &c., &c.; oranges, lemons, limes, bananas, and plectly pears; luscious grapes, red and white, in huge tempting clusters; persimmons of Japan, loquats of China—there they lie in profusion. No tender hothouse fruits wrapped carefully in pink tissue paper and softly lodged on cotton wool, but sturdy, ruddy, fruit, grown under the fair open sky and incessant sunshine of this favoured climate. Let our wanderer taste one of those great golden-hued Bartlett pears; its juicy pulps meets in the mouth—five pence will buy a dozen such; or invest five cents in that large bunch of purple grapes well over a pound in weight. Such a cluster would cost ten shillings in London. Those giant peaches may be bought at thirty or forty cents for a basket of some three dozen, and they will prove ripe and juicy. There is a Cantaloupe melon as big as your head for fifteen cents, and a smooth green water-melon, much bigger, for the same price.

Let us stroll out into the busy streets. Here is an old fellow driving a brisk trade in five-cent plates of fruit arranged temptingly along his stall. You may take your choice. There is a plate of three fine pears elbowing the counter-attractions of three lovely bunches of grapes, black, red, and white, a pyramid of peaches, another of plums, a dish of varied fruits, all ripe, fine, and luscious. At every street corner the small vendor is to be found with his five-cent plates, and in every street one or more fruit shops. Where is all this fruit grown? In all parts of the State; the wide alluvial plains, the warm, sheltered canyons, and the sunny slopes of the hills, all have their orchards and their vineyards, from which peep the pretty and comfortable houses of the fruit growers. Tons upon tons are shipped East to supply the New York and other markets; other tons are canned, bottled, and made into jams and jellies for distribution to the markets of the world; other tons again are dried and pressed. California has already a reputation for "canned" fruits, and is gaining experience and skill in the manufacture of dried prunes, raisins, figs, and such like, once the monopoly of the Mediterranean countries.

The wine makers too, are adding each year to their skill and experience. Thousands of acres are now planted with vines of the nobler sorts, and while the already excellent and cheap claret made from the Zinfandel grape is growing better each year, the epicure will, it is hoped, soon find in the California market wines of as delicate bouquet as those which are becoming so rare and costly in Europe. Fruit-growing in California is no longer so profitable as it has been. Like all profitable enterprises, it has been overrun by speculators, who have recklessly planted thousands of acres of trees and vines, which are now coming into bearing, and glutting the market with their produce. The probable losses to many growers, and consequent reaction which must result in the near future, and are, indeed, already making themselves felt, will do much to restore the balance, and leave to the legitimate fruit-grower the steady profits of a pleasant calling.—*Pall Mall Gazette*.

MILK FEVER, OR PARTURIENT APOPLEXY.

THE following bulletin by the Professor of Veterinary Science in the Michigan State Agricultural College treats of a subject of importance to every owner of cows, and the treatment described is worthy of trial by any one who finds one of his cows suffering from an attack of the disease. The treatment commends itself by its simplicity and the ease with which it can be used under almost all conditions:—

In compliance with section 2, of an Act passed by the legislature recently adjourned, providing for the dissemination of information gathered by certain departments of this college, I beg to submit for consideration some very favorable results, I have obtained from the application of cold wet packing in the treatment of parturient apoplexy, or milk fever. Before, however, taking up the practical part of the subject, I may be pardoned, if I notice some of the chief characteristics by which this disease may be recognized, for this is a complaint which is not familiar, except indeed by name alone, to many of those breeders who only raise one or two animals annually, and unfortunately the number of animals that are invaded by it, is on the increase from year to year, in direct ratio with the improvement in milk cattle. It is very important that it should be detected, as soon as it makes its appearance, for I do not know of any disease where the old adage of a "stitch in time, etc.," can be more appropriately applied, than to the one under consideration, and the remedy which I shall further on allude to, has, in those instances that I have applied it, "nip ped the disease in the bud."

SYMPTOMS.

In those cases which I have had an opportunity of observing in the early stage, the first evidence of something being wrong was an exhibition of general restlessness, and loss of appetite, accompanied in many instances by rigors, or in other words a chill; which is often more or less confined to the hind quarters; this is usually followed by what is called by veterinarians, paddling of the hind feet, which consists in an uneasy movement of them, during which they are lifted, first one, then the other, from the ground, and put down again, not exactly with a kick, but rather a paddling like motion. At this stage there is usually a profuse discharge of tears from the eyes, the countenance is one of anxiety and distress, when singularly enough, the mother seems to lose all interest in her offspring, and will not notice it. If the affected animal is required to walk, it will do so with a staggering gait, or will even drop behind, or fall down.

The secretion of milk is much diminished, or perhaps stopped altogether. The above may be considered as the symptoms of the first stage to be followed, however, in somewhat rapid succession by those of

THE SECOND STAGE.

In which paralysis, and impairment of those organs which control consciousness, are most noticeable. The unfortunate animal will lie or fall down, and is often unable to rise, although it may make frequent attempts to do so, but eventually gives up, completely discouraged. At this point the head will be flung around to the right side and kept there persistently. The muscles upon the side of the neck become firmly contracted; even when the head is brought by force into its natural position, a sort of kick will appear in the side of the neck towards which the head is thrown, and which I have seen remain for some days after the animal was able to walk about. In other instances I have seen cases where the animals would rest their heads upon their horns, thrown back against the floor. In these cases care must be taken to prevent the animal from breaking off the flaps, or horn cores, by the force they occasionally use in flinging their heads about.

IN THE THIRD STAGE,

The animal drops into a profound sleep, when it will lie almost motionless, breathing, it may be, with a loud snoring sound, the cheeks becoming inflamed at every expiration; things go from bad to worse until death eventually closes the scene. Once in a while though one will meet with a case where this profound sleep appears to do the animal a great deal of good, for it will awaken to make a rapid recovery.

The foregoing manifestations, together with others not perhaps so perceptible, will be observed to a greater or less extent in every pure case of this disease.

TREATMENT.

Before describing the manner of applying the pack, I would like to say a few words as to how I came to adopt this form of treatment. In short, some time ago I was called upon to visit a cow attacked with some unknown disease (unknown to the owner). I was not long in determining that I had a case of parturient apoplexy to deal with, but in passing my hand over the animal's body, during my examination I observed it to be bedewed with moisture, which I thought was water, it being a wet day, and asked the owner how he came to leave so sick a cow out in the rain to which he replied that "she had not been out in the rain, but had been in the stable where I was; then examining her, since she was first taken." I must admit I was somewhat astonished, but a closer examination revealed that the moisture was sweat from the skin and not rain-water. This most unusual occurrence caused me to reflect before proceeding with my usual treatment, but soon concluded that nature was doing all she could to throw off, as it were, the disease, and did not feel disposed to interfere with any of my own medicaments, but rather tried to help nature in her effort, by placing plenty of dry straw around the cow, and a light, warm blanket over her, and after attending to some of her more immediate wants, it being late at night I left her, not before, however, telling the owner to come for me if she showed any evidence of not progressing favorably, and explained to him why I did not there and then

give the cow some medicine. The next morning she was much better, and in the afternoon was able to walk about, although paralyzed and unable to rise the night before. With careful feeding she made an excellent recovery. This case and others have made a very strong impression on me that the diaphoretic (a remedy which causes a discharge of perspiration from the skin) form of treatment is the sheet anchor in this disease, but the difficulty was to get one whose virtues were not more than counterbalanced by other circumstances. I have often longed to try the Turkish bath in these cases; unfortunately this kind of diaphoretic is not one that can be carried about conveniently, so that it becomes impracticable. I have tried the hot blanket with variable success. The difficulty with them is the trouble of applying them properly, and it is hard to get attendants to make the changes at the proper times, or to do so in such a way as to prevent the animal from getting a chill; then the hot water is often inconvenient; the boiler perhaps being some distance from the stable, with many minor difficulties perhaps too numerous to mention. The cold wet pack has from time to time been brought under my notice, and eventually I was induced to try it, and I must say that in my experience it has done all that could be desired. Then it can always be procured; not only that, but it can be procured readily, which is an invaluable advantage in this disease, for before the malady has had time to prostrate the animal, you have it headed off as it were, and before other remedies would have time to act, with this on the animal is often on a fair way towards recovery.

Before applying the cold wet pack, the owner or attendant must make up his mind to do the work thoroughly, or perhaps it will be better not to do it at all. So for the benefit of those who wish to try it, I shall now describe the manner in which I proceeded in detail. Before putting on the sheet, I consider it a good plan to rub the animal, say for four inches on both sides of the centre of the spine, and from the withers to the tail, with the best mustard, made up as for table use, and rub in for about 15 minutes. This may be left on for two days. To apply the pack, take say a bed sheet and wring it out of cold water and wrap it around the cow; every part but the head may be covered; if one sheet is not large enough, sew two together. On top of the sheet place say two pair of the lightest and warmest blankets that can be obtained. Nothing could be better than these light cotton batting comforters, so popular now in every household. Over all place an oil cloth of some kind, or other close fabric that will keep the heat in. Those parts of the body, the legs, etc., which are not covered by the sheet must be covered with straw, or other material, for they must be kept warm. In the course of half an hour or so after the pack has been applied, the body will be thrown into a profuse perspiration, and will continue so for an hour or so, but as soon as the skin begins to get cool, then preparation must be made for a second pack, and the changing must be quickly effected, or too long exposure will do more harm than the next pack will do good. If the wet sheets can be changed without removing the top coverings all the better. Some animals are exceedingly restless during the progress of this disease, and it is these that give so much trouble and require constant watching to keep the pack in its place. Others will show much uneasiness of the head, which may be modified by tying cold wet cloths around and across their horns. With regard to the length of time the pack requires to be applied I cannot say; in my own experience the symptoms have always been relieved in twelve hours, sometimes in half that time. After it is taken off, care must be taken that the skin is kept moderately warm. While the symptoms last the cow must be kept from throwing itself over on its side; this may be done by packing sacks filled with straw against its sides. The milk should be drawn several times a day, and the bladder emptied; this latter operation requires the assistance of a veterinarian to show the attendant how to do it. When certain complications occur, such as distention of the rumen with gas, etc., the remedies which are calculated to relieve them must be used, but I think these should be left to a veterinary surgeon. But to return once more to the pack, I may say that I have had experience with it which justifies me in saying that it will often overcome the disease without any other treatment, and even if it does not in all instances it will at all events keep it in abeyance until proper veterinary assistance can be procured. When the animal recovers it should be fed for a few days, say a week, on soft diet, and receive a little daily exercise.

E. A. A. GRANGE,
Professor, Veterinary Science.

September 1, 1885.
—*Farmer's Review.*]

THE ADULTERATION OF MILK.

At the Milk Conference in connection with the London Dairy Show lately, the following paper was read for Sir J. B. Lawes by Mr. Jas. Howard, M.P.:

The milk trade in the metropolis is at the present time in a somewhat unsatisfactory state. It is not merely that the producer receives a very low price for the milk he supplies, for in this he merely shares the fate of all those who obtain their living from the products of the dairy, but because the law which makes it a punishable offence to sell milk that has been adulterated—or what in most cases is milk diluted with water—does not recognize as a fact that the quality of the milk from some breeds of cows is so high that even if it were mixed with a considerable amount of water, it might still be richer than genuine milk, which was the product of other cows fed on a

lower description of food. The result is that the law in regard to the sale of milk unintentionally gives every encouragement to the sales, not of pure unadulterated milk, but of poor unadulterated milk.

It is quite evident that under the present system many breeds of cows which produce a high quality of milk are altogether excluded from the dairy of the farmer, in consequence of his not being able to get a higher price on account of its better quality, while he cannot afford to sell it at the same price as the ordinary milk. As a matter of fact, the production of the largest quantity of genuine pure milk is the great secret of success in the present state of affairs.

At Nothamsted we have recently been investigating several questions with regard to the production of milk, and our investigations will be continued. Now, suppose we found that, by a certain combination of food, a milk of an unusually low percentage of solids could be obtained, would not this be hated by the milk-selling farmers as a far greater boon than any process by which a much higher percentage could be produced? It may possibly be said that such a milk would not be saleable, but this is quite a mistake. It is true that dealers might raise some objection, as although they will not pay for high class milk according to its value, still they like to have it. The public, however, would buy the low percentage milk readily enough. It does not further follow that the milk of poor quality would taste poor: we have lately shown that milk from ailage, which, from its colour and taste, appeared richer than the milk from mangels, was not so rich in reality; and it is a well-known fact that the purest sugars are not those which taste the sweetest. At all events, without anticipating what may be in store in the future, it must be admitted that the principle of offering a premium for the cow, which produces the largest quantity of poor milk, is one which requires some modification.

It is quite evident that the weak spot of the present arrangement is the want of some standard or basis on which the trade shall be regulated. To say that a person shall be punished for selling adulterated milk, and then to leave the definition of what is and what is not pure milk to experts and magistrates—who possibly may differ considerably in their views upon the subject—is hardly fair upon the producer. It is, however, much more easy to point out the objections to the present system, than to suggest a remedy. Assuming it is desirable that a standard should be fixed defining what is pure milk—the question then arises, What is the standard to be? If it were fixed very low, so as to include the poorest milk ever produced, the result would be that all milk would be diluted down to that standard. If, on the other hand, a high standard were fixed, it would necessarily exclude some very poor, but yet genuine milk.

Let us assume that a certain quality of milk was agreed upon by producers and experts as a fair average to represent genuine milk, and that this was declared to be the standard. The result would be that those who were so inclined would be enabled to keep cows yielding a very high quality of milk as it would no longer be an offence to dilute such milk to the fixed standard. On the other hand, why should not other qualities of milk be sold, provided the seller stated the amount of dilution to which it was subject?

There is another part of the milk trade which requires some reform. I allude to the large cost incurred in the distribution of the milk, which affects it seriously as a cheap food. The sky-blue liquid which used to be sold in London had no pretensions to be called a food, but genuine milk—were it not for the cost of distribution—would be a very cheap food, especially for the young, and although milk is not so well adapted to be the food of grown up people as meat, it is a perfect food for children, and, at the same time, very much cheaper than meat.

I do not know how far the police regulations would limit of such a proceeding, but if milk, instead of being sent up to its destination in churns, could be conveyed by rail in a tank upon wheels, it might be sold direct to the consumers with very little addition to the cost of production, and it would thus become a staple article of food to the poor.

If the demand for milk is to keep pace with the increased supply some such process must be adopted, and the producer and the consumer must be brought together without the intervention of the middleman. Mayfair and Belgravia may still continue to receive their daily supply through the middleman, if such be their wish, but the time is come when an effort should be made to furnish the teeming population of the metropolis with cheap milk as a portion of their daily sustenance.

In the course of a discussion which followed, Mr. Barham threw out a suggestion for cheapening the distribution of milk which appeared to elicit approbation from the meeting. This was that the public ought to be content with one delivery a day in winter, and that if this took place in the afternoon the cost of distribution would be so far lessened that the price to the consumer might be considerably decreased. The same speaker defended milk dealers from the charge brought against them by Sir James Caird of making exorbitant profits, showing that few of the milk companies were paying good dividends to their shareholders; that they never heard of milk vendors making fortunes, like brewers and middlemen; and that, fairly estimating the immense labour and persistent attention required by consumers, and devolving on those who conducted the milk trade, the disproportion between the wholesale and retail rates of milk was by no means so great as in those of many other articles. He thought, however, that in good times the entire milk trade might become revolutionised, as soon as the public had been educated sufficiently to perceive that separated milk is a more healthy food, and in every way more suitable, both for children and adults than whole milk containing the cream. By separated milk Mr. Barham meant, of course, skim-milk; but the variety of it which has been separated from its cream by a mechanical separator, or other means, immediately after being

drawn from the cow, and thus in a condition of perfect sweetness and freshness.

Other speakers fully endorsed this opinion, and it was stated that separated milk might be retailed at about one-half the price of whole milk.—*North British Agriculturist*.

THE CAUSE OF MILK SICKNESS.

The prevalence of poisonous plants in wild woods, pastures and on ranges requires a correct knowledge of their habits of growth, characteristics and appearance, as necessary to all who herd or pasture stock where such plants may be suspected. The reported outbreak of milk sickness in some timbered pastures of southern India, and in other similar localities, lately, recalls the time years ago, and occasionally since when farmers in infected regions dared neither use the milk of their cows nor the butter made from the milk. Investigation at that time seemed to point to a plant of the genus *Eupatorium*, yet no really conclusive evidence seems to have fixed the real source definitely. According to a statement of Prof. N. S. Townsend in the Ohio report of 1873, Mr. John Rowe experimented with plants of white snake-root, producing fatal results in a cow, and attested by a number of reputable gentlemen. In 1859 Mr. W. S. Vermilya, in Ashland county, Ohio, is said also to have produced the disease called milk-sickness with this weed. On the other hand, cases have been noticed in wild pastures said not to have contained the plant. Hence there is yet a large difference of opinion in relation to this matter, and the writer can only record such facts as would seem to be well borne out, in hopes that careful investigation by competent botanists will be made.

The outbreak seems generally confined to dry seasons, and the difficulty was supposed to arise from drinking the water of mineral springs, to which cattle were obliged to resort at such times. The infection was at last fairly relegated to certain plants found in low, moist situations in the timber, first suspected from the fact that animals kept on cultivated pasture were not affected.

The difficulty was at length fairly well traced to eating the plant known as white snake-root (*Eupatorium ageritoides*), and fed to cattle, horses and sheep, they become affected with all the symptoms of the disease known as "trembles" and "milk-sick." There are many varieties of *Eupatorium* (Thoroughwort) valuable in medicine. The plant in question, white snake-root, is common in rich woods and undergrowths in the North, specially in moist situations. The leaves of this plant are broadly ovate (oval, but broader near the base), and on long petioles or stems. They are pointed, coarsely and sharply toothed, thin, and four to five inches long. In open fields the weed grows near fences, old logs, stumps, etc., where it may get the requisite moisture. It will not grow in a meadow or pasture except in the situations indicated. It is eaten by horses, cattle, and sheep, but not naturally. That is, they eat it only when other food is scarce, or when starved to it, but with eating the taste increases. Its decrease with settlement, and the added fact that only in seasons of short pasture it is injurious, should cause every farmer in regions where it has ever been known to do damage to seek it out and destroy it.—*Chicago Tribune*.

EGGS IN WINTER.

One of the essentials for inducing hens to lay in winter is warm, comfortable quarters. With lumber and building paper used so as to furnish air spaces in the sides and roof, and with no chance for cold air to come in at the bottom, a chicken house can be made so warm that when well stocked with chickens it will scarcely freeze inside in the coldest weather; the heat generated and given off by the chickens will keep the temperature above freezing. But in such case, unless provision is made for ventilation, the air will become impure, and the chickens will sicken and die. How this ventilation can be arranged is shown by the following from the *New York Tribune*.

The editor of a leading poultry paper has said that a hen house sunk into the ground is objectionable because, being inclosed on two or three sides, it cannot be ventilated. Now, there is no more difficulty about ventilating a cellar than a garret, if there are live animals in it to generate heat enough to make a change of air desirable. Another poultry writer says hens must be let out into open sheds to take the air every winter day. I kept, last year, twenty-five shut up three months in a house as near air-tight as I could make it, except the ventilators. The hens were happy, healthy, and laid every day, and, what was most remarkable, almost every egg set hatched. I carried a palful of eggs to St. Albans, eight miles, on the bottom of my buggy, expecting to sell them to my grocer, but I met a man who picked out thirty of them, and took them in a common lumber-box double waggon over the hills to Fairfield, about six miles more, and every egg produced a live chick.

Dr. Riggs, of Connecticut, has a brick henery four feet under ground and five feet above, made to be warm; he wanted eggs in winter when they brought fifty or sixty cents a dozen. The pullets were made to lay four months after they were hatched. But he found bad air in this henery, which could not be got out; that was a point not thought of when he constructed it. So he made a flue reaching up to the gable of the roof, and running down to within four or five inches of the bottom of the henery. He had no difficulty after that in making that room just as nice in its atmosphere as your barn or house. The draught was altogether up. Air enough came in, although the windows were as tight as they could be. The result was pure air; chickens never diseased; they were healthy and happy, crowing and cackling, and laying nice eggs. There is no need of freezing birds' combs; I have kept Leghorns for years and never had a comb freeze.—*Farmers' Review*.

INDIAN MILLS.

The annual statement issued by the local Mill-Owners' Association, showing the number of Cotton Spinning and Weaving Mills in India on 30th June last, is an extremely useful compilation. The latest return is a great improvement on its predecessors, and Mr. Marshall, the Secretary of the Association, is to be congratulated on the issue of a statement which will be perused with interest by all engaged in the trade and out of it. To a correspondent, we are also indebted for a statement showing the progress of Bombay mills during the past twenty-one years, and a second one showing the growth of the entire Indian mills in the last ten years. These returns are interesting appendices to the mill-owners. In the whole of India, on 30th June last, there were 87 cotton mills, excluding five which are believed to exist, but particulars of which are not forthcoming. If these are taken into account, 92 is the total. Of the 87, 68 are in the Bombay Presidency, 49 in Bombay and suburbs, and 19 up-country. There are two in the Central Provinces, one in Central India, one in the Berar, one in Hyderabad, Deccan, three in the North-West Provinces, six in Bengal (in Calcutta), and five in the Madras Presidency. Of those of which information is wanting, one is being erected at Bangalore (in Mysore), one in Tinnevely, one in Travancore, another in Nizam's territory, and one in Pondicherry. Confining ourselves, however, to the details of the 97 known mills, we see that the total paid up capital is put down as 766½ lakhs, while the number of spindles is given as 2,145,648 and the number of looms as 16,537. The average number of hands employed daily is entered as 67,186, and the consumption of cotton in the past twelve months as 596,749 bales of 392 pounds each. Ten years ago but 47 miles were at work in the country, possessing 1,100,112 spindles and but 9,139 looms, consequently there has been an increase in the decade of 36 per cent in the number of the mills, 49 per cent in the spindles, and 45 per cent in the looms. Previous to 1879, details are not available outside our own Presidency of the number of hands daily employed nor of the annual consumption of cotton, but in the last seven years, in round numbers, the army of workers has increased from 43,000 to 67,000 and the consumption of the raw material from 267,000 bales (892lbs. each), to over 596,000 bales, or say from 936,000 cwts to 2,088,000 cwts. This increase is very remarkable, and the only pity is that it has not been a greater financial success. Like everything else of late, the production has outstripped the consumption, and the result of the working of the majority of Indian mills during the past eighteen months is the reverse of profitable. The lesson taught in 1879, when some eight or ten concerns went into liquidation, was speedily lost, and with a return to brighter times the public again rushed in and assisted promoters to rapidly increase the number of the mills. It is true that of late we have not witnessed the dark scenes of 1879-80 repeated, but we have seen the bulk of the mills working either at a dead loss, or making just about enough to cover expenses. It has been rare, indeed, to hear of one that had made a profit. The present lull in the promoting world will do good, and ere long, when trade revives, there is little doubt that honestly worked and managed concerns will be able to make good returns to their shareholders. The coming year promises hopefully. A large crop of cotton is almost assured, and as our Yankee friends are equally well off, the price of the raw material is bound to give way, and spinners and manufacturers may look with cheerfulness to a brighter future. Turning to our correspondent's statement of the progress of Bombay—Island and Presidency—mills, we notice that while in the twenty-one years the number of the local mills has increased from ten to forty-nine, the up-country ones have increased from three to nineteen, the total advancing from thirteen to sixty-eight. The number of spindles has increased locally in round numbers from 250,000 to 1,347,000 and up-country from 36,000 to 303,000. Total increase from 286,000 to 1,650,000. The number of looms has increased locally from 3,400 to 12,000, and up-country from 200 to 2,600. Total from 3,600 to 14,600. In 1865, but 7,400 persons—6,600 in Bombay and 800 up-country—were daily engaged in the mills of the Presidency. This year over 51,000 were similarly occupied, of which nearly 42,000 were employed in the city and suburbs. A record of the consumption of cotton previous to 1873 is not obtainable, but in that year we see the local consumption is given as over 67,000 bales (of 392 pounds each), and the up-country has 7,500 bales, a total of close on 75,000 bales. Twelve years later—30th June this year—the local consumption is stated as over 392,000 bales and the up-country as over 73,000 bales a total of nearly 466,000 bales.—*Times of India*.

HOLLOWAY'S PILLS are the medicine most in vogue for curing the multifarious maladies which attack humanity when wet and cold weather gives place to more genial temperatures. In short, these Pills afford relief, if they fail of being an absolute remedy in all the disturbances of circulation, digestion, and nervous energy, which at times oppress a vast portion of the population. Under the wholesome, purifying, and strengthening powers exerted by these excellent Pills, the tongue becomes clean, the appetite improves, digestion is quickened, and assimilation rendered perfect. Holloway's medicine possesses the highly estimable property of cleansing the whole mass of blood, which, in its renovated condition, carries purity, strength, and vigour to every issue of the body.

THE COCA PLANT.

FROM Secretary of State for India, to his Excellency the Right Honorable the Governor-General of India in Council, dated India Office, London, 6th August 1885, No. 69, Revenue:—

In reply to your letter, No. 6 (Agriculture), of 28th April last, asking for some information regarding the preparation, for the market, of the leaves of the coca plant (*Erythroxylon coca*) of South America, I herewith forward copies of reports on the subject received from Sir Joseph Hooker and Surgeon-General Edward Balfour, to whom your letter, with its enclosures, was referred.

ENCLOSURES.

Letter from W. J. Thimelton Dyer, Esq., to J. A. Godley, Esq., C.E., dated Royal Gardens, Kew, 4th July 1885.

I am directed by Sir Joseph Hooker to acknowledge the receipt of your letter (R. S. and C. 876) of 23rd June, transmitting copy of a letter, with enclosures, from the Government of India respecting the preparation, for the market, of the leaves of the coca plant (*Erythroxylon coca*), and asking for information upon the subject.

I am to say, in reply, that nothing can be added to the statement as to the method of drying made by Deputy Surgeon-General G. Bidle, C.I.E., in the pamphlet upon coca recently published by him at Madras. New drying in the sun appears to be the whole art of the matter.

I am also to state that, from a letter received from Mr. Lawton, the Director of Government Cinchona Plantations, Parks, and Gardens, Nilgiris, dated 23rd April last, there is reason to think that the difficulty met with had been overcome.

Letter from Surgeon-General E. Balfour, to the Under Secretary of State for India, dated 2, Oxford Square, Hyde Park, London 7th July 1885.

Your letter of 23rd ultimo enclosed a communication from the Government of India asking information regarding the mode of preparing coca leaves for the market; also instructions regarding the cultivation of the plant, and how the leaves are commonly used in South America. I have given a very considerable amount of information on these points under the headings "Coca" and "Erythroxylon" in the 3rd edition of my *Cyclopædia of India*; but, on receipt of your letter, I waited on Mr. Gale, of Messrs. Bell and Co., who has given me much information, and has obligingly obtained, from Mr. Tanner, the accompanying samples of the leaves, flowers, and fruit.

2. Mr. Gale is of opinion that the leaves, when drying, naturally retain a flattened form, just as some leaves do, and it is considered unlikely that any particular drying process is followed. But the Foreign Office, through her Majesty's Consuls, could obtain all the details as to the cultivating, and as to gathering, drying and packing the leaves, with the ordinary market price in the locality, and the various modes in which the leaves are used. I could apply to the Consular Department to obtain this information, though such an application might, perhaps, come better from yourself. I have, however, ascertained that, at present, the records of the Foreign Office do not contain any notice of this plant.

3. I may here mention some points of interest which have become known to me whilst I was collecting the information necessary for replying to your letter.

The leaves, as seen in the market, are of the greenish hue, observable in the accompanying sample.

The price of the leaves has fallen so low, with a prospect of a still greater fall, that it is not, at present, deemed advisable for any grower to incur any large expenditure for its cultivation.

I am informed that Mr. Howard recently bought up all the leaves in the market at three shillings the pound; and, as a consignment of 30,000 lbs. is on the way for New York, Germany, and London, the price is expected shortly to fall to six pence the pound.

It is brought to this country in bags, in which the leaves are found much broken.

At present, about ten grains of the cocaine alkaloid are obtained from one pound of the leaves; and, on the 26th June, Messrs. Bell and Co. were selling it to medical men at one shilling the grain, and a retail price of one shilling and three pence the grain.

4. Besides the use of the cocaine alkaloid as an anæsthetic in ophthalmic surgery, and during operations on the mouth, ear, and throat, pharmacologists have already prepared from the leaves a medicinal wine and an extract, and I think it possible, even probable, that the leaves may take their place as a tea plant, or as a valuable addition to the tea and coffee of commerce.

5. Also, it is yet to be ascertained whether the species of *Erythroxylon* growing in the East Indies may possess properties identical with that of the *Erythroxylon coca*. When this view occurred to me, I asked Surgeon-General Short to ascertain its importance. I meant that the leaves might be chewed as a masticatory, in the manner that they were used by Western the pedestrian; but Dr. Short has not informed me if he tried that mode. He sent, however, to Mr. Edmund Blyth, the Analyst for the Marylebone district, twenty pounds of the leaves of the *E. monogynum*. That quantity was too small for experimenting with, but Mr. Blyth authoritatively ascertained the presence

of an alkaloid. There would be a valuable addition to the food plants of the whole human race, if it be ascertained that the Indian species of *Erythroxylon* possesses, like the *E. coca*, the stinging properties of tea and coffee.

6. The institution of enquiries of this kind has ever formed a prominent feature in the British administration of India, but I think that this is one meriting investigation. But under the headings "Coca" and "Erythroxylon" in my *Cyclopædia of India*, just published, where I have noted the alkaloid and the species of genus, it was necessarily only with the brevity requisite for keeping each article in due subordination to the other 35,000 which the book contains. And if the suggested inquiry be undertaken, it seems desirable that it be conducted, as regards the verification of the plants, under the superintendence of Sir Joseph Hooker, in order to make certain that the proper plants have been gathered from, as the species of this genus have presented difficulties to botanists, and the plants and their species, as they now stand, have been allotted to other genera and other species.

FOOT-AND-MOUTH DISEASE.

Mr. JAMES HOWARD, M. P., Clapham Park, Bedfordshire, writes:—After having inflicted prodigious losses upon the country, this insidious disease was some months ago after great efforts and an infinite amount of inconvenience, practically stamped out in the three kingdoms; dying embers have, however, from time to time been rekindled in various places, but instead of treating these isolated outbreaks as a fire would be treated, the Agricultural Department of the Government has contented itself with methods which have proved so dangerous and disastrous in the past—viz., isolation and veterinary treatment. In order to spare the life of a few animals, instead of turning them into beef and mutton a few weeks before their time, the country has been exposed to the most serious risks, great expense has been entailed upon localities, and breeders and exporters subjected to a vast amount of inconvenience and loss. Breeders of pedigree stock have much reason to complain, for in many cases they have been prevented sending their animals abroad in consequence of other countries prohibiting importation, whenever we are unable to show a clean bill of health in respect of foot-and-mouth disease.

Not many days ago no less than eleven centres of disease existed in three different counties, and more than a hundred animals were affected. If these animals had been landed at our ports not a moment would have been lost in slaughtering them, and had a single day been suffered to elapse the indignation which would have been expressed at the neglect can readily be imagined.

I would ask, are not these centres of disease in the heart of our great grazing districts infinitely more dangerous, than if at either of our ports of landing each with its isolated "foreign animals wharf"?

What must the dwellers in towns think of the sincerity of certain alarmists and exclusionists when the presence of disease in the heart of the country is tolerated by them with so much equanimity. Surely all Mr. Chaplin's former valiancy has not oozed out in the office of his department. I have long contended that isolated outbreaks of contagious disease, should be treated like the outbreak of a fire, and Mr. Chaplin formerly agreed with me on this point.

Section 29 of the Contagious Disease (Animals) Act, 1876, is as follows:—"The Privy Council may from time to time make such orders as they think fit, subject and according to the provisions of this Act, for directing or authorising, in case of the existence of any disease other than cattle plague or pleuro-pneumonia, slaughter of animals by local authorities, either generally or in particular instances, and in all or any of such cases payment for compensation of the same by local authorities out of the local rate." This clause, I contend confers power upon the Privy Council in respect of foot-and-mouth disease. Lord Carlisle and others have taken a different view, alleging that the methods of dealing with this disease are prescribed by sections 22, 23, 24, 25, and 26, under the heading "Foot-and-mouth Disease," and therefore section 29 is not applicable, and is intended only for other diseases than those specifically provided for by the Act.

In reference to this contention, I would point out that the method of dealing with cattle-plague and pleuro-pneumonia are also prescribed for by separate clauses and under their respective headings, and yet section 29, while it refers to the above diseases, makes no mention of foot-and-mouth complaint; surely if the intention had been to exclude the disease it would have been sacrificed as well as the other two; but, whatever the intention of the authors, the fact remains that foot-and-mouth is not excluded. The reason of the exclusion to my mind is obvious; in the clauses relating to plague and pleuro, powers to slaughter and to pay compensation are conferred, while in the clauses relating to foot-and-mouth no such powers are given; hence the particular phraseology of clause 29, and the provisions which it makes for slaughter and compensation; it is as much as to say that if the foregoing regulations fail, then the Privy Council are endowed with more general powers, for the clause is headed, "Slaughter in Disease and Compensation generally."

The disease is again on the decline, and is now, as it were, in a nutshell; but the time for movement of cattle throughout the kingdom is upon us. Seeing how great are the perils of another wide-spread attack of the insidious and dangerous plague, will not the wisest step be to stamp it out, while within manageable limits? If a wider interpretation be given to clause 29 than was intended by its framers, who, I ask, will be endangered?—*North British Agriculturist*.

* *E. Burmannianum*, Griff., of the Eastern Peninsula, Andamans, and Tenasserim, is *E. retusum*, Baur.
E. Kunthianum, Willd., Ckt., of Eastern Bengal and Siam.
E. lanatum, Wight, H., Western Peninsula, is *Setaria lan-colata*, Thw. and *E. erythroxylon*, Wight.
E. lucidum, Moon's Cat, of Ceylon, is *Setaria acuminata*, Arn. Wight, Thw.
E. monogynum, Moz. Cor. Fl. of Ceylon and Western Peninsula, is *E. Indica*, Seidl., and *Setaria Indica*, D. C.
E. obtusifolium, Thw. Ba., is of Ceylon.
E. siccocaryoides, Fenzl., is of Mauritius.

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels constive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often-times there is a palpitation of the heart, and the patient fears he may have heart-disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARY-STREET, PETERBOROUGH.

November 29th, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer described it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Sd.) VINCENT A. WILLS,

Chemist-Dentist, Merthyr Tydvil.

To Mr. A. J. WHITE. Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constiveness,

Preston, Sept. 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

To A. J. WHITE, Esq.

(Signed) W. BOWKER.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint, with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (having continued taking it), I am glad to say that I am a different being altogether. It is said of certain pens that they "come as a boon and a blessing to men," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CAREY B. BERRY,

Baptist Missionary.

Hensingham, Whitehaven, October 18, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(C.)

(Signed) JOHN H. LEAFHURST.

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA
SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A
WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DEBILITY, ATTENUATION OF BODY, ERUPTIONS, LASSITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the sequelae of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of *Wilkinson's Sarsaparilla*, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your *Essence of Red Jamaica Sarsaparilla* cured me of a Torpid Liver; all other remedies failed."—*Earl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palm, Cotton, Cardamoms, Kola, Cocoa, Cinnamon, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at Observer Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the *T. A.*, as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12.—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Re. 18), carriage prepaid.

As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, NOVEMBER 21, 1885.

[No. 47]

Editorial Notes.

We are unable to give the usual official health, crop, and weather report for the week ending the 11th instant, as, owing to the change of Government from Simla to the plains, it has not been published this week.

.

It has been decided by the Government of Madras that all candidates for employment in the grade of Sub-Assistant Conservator, whether selected from the ranks of Forest Rangers or appointed direct, must in future be required to undergo the course of training at the Dohra Doon Forest School.

.

MR. CHISHOLM, the Consulting Architect to the Government of Madras, who was asked for his opinion in reference to the value of Coimbatore lime-stone, has stated that it is not a sound building stone, being too chippy to admit of fine carving, and too soft to receive a lasting polish. He believes, however, that if the quarrymen worked deeper, a much sounder material could be put in the market; at present, though much handsomer, it is far inferior to Pallavaram granite and three or four times as costly, delivered in Madras. He cited as an example the columns of the Anderson Memorial opposite Government House which are of the pink Coimbatore stone, and were originally highly polished. The capitals and bases are of white Coimbatore limestone and exhibit its sculptural properties. Also, that the corbel columns and capitals on the exterior face of the carriage exit of the new Central Station, Madras, are also of Coimbatore limestone. He does not think the public generally notice any difference between these stones and the cheaper and more trustworthy local stones.

.

Messrs. LLOYD & Co., Managing Agents for the Chenga Tea Company, have addressed the following interesting letter to the Agri-Horticultural Society of India, on the important subject of Tea Blights :—

"A short time back we handed you specimens of mosquito blight and blighted leaf sent down by our Manager, and in continuation, we beg to place before you the following remarks, which form part of his monthly report :—

"Mosquito Blight had spread all over the cultivation on the Factory and Bangalore side, as well as that portion called 'Junglu-katu,' so that the yield of leaf was considerably lessened by it. Specimens of the fly and blighted leaf were forwarded to Calcutta for Managing Agents' inspection and satisfaction to show damage done. I have every reason for believing the species of Toon trees planted along the roads of the garden are the great harbingers of this pest, for I have noted both in the hills and here these trees are always more or less blighted the whole year round, and the tea bushes under them and near by are always the first to be attacked : wherever toon trees are on the garden, the blight is worst, so that I would recommend every tree being cut down, as they are perfectly useless and valueless—all leaves and small branches to be burnt, the stems or trunk can be used for engine wood."

"This is the first time that we have heard the presence of this pest attributed to the growth of toon wood trees, adjacent to the Tea. Can you inform us whether you have any record supporting Mr. Helge's theory."

THERE has been a good deal of discussion in the Southern Presidency regarding a scheme for carrying out experiments in diversified cropping. The Agricultural Reporter to the Government of Madras has submitted certain proposals, which have been commented upon by the Director of Agriculture, and both have been reviewed by the Board of Revenue. The following order of the Government (condensed) will give a fair idea of what is meant by diversified cropping, and what the Government have in view :—

The Government do not consider it necessary that any preliminary inquiry should be undertaken as to "what is the least amount of water required to raise a remunerative crop of paddy," or as to "whether the possibly irrigable area can be largely increased." There is no doubt that the area of irrigated land can be largely extended, provided a sufficient supply of water is available; and it is for the precise purpose of ascertaining whether the existing supply can be advantageously economized so as to provide a large margin for extension that the proposed experiments have been suggested. As to the amount of water required for paddy cultivation, it is not likely that anything will at present be added to the information contained in G.O., 21st May 1885, No. 473 I. The subject is one that has long engaged, and is still engaging, the attention of the Irrigation Department, but there is no reason why, pending the result of such researches, the experiments proposed by the Director of Agriculture should be delayed.

What is wanted is not "land not affected by previous treatment or surrounding irrigation," but land which has for some time been cropped with paddy and on which the crop has presumably deteriorated in consequence, and become subject to disease. It is with a view to the improvement of land of this sort, of which there are, it cannot be doubted, large areas in this presidency, that experiments are proposed. Land of the kind desired by Mr. Benson would, even if discoverable, be in no way typical of the rice lands of the country generally.

.

A "STAFF to conduct and record the progress of the experiments" is not necessary, if the experiments are to be conducted, as proposed by private landowners, under the supervision and with the advice of the department. All that is required is, that progress should be watched and reported by a competent officer. So, again, there is no need to await "more knowledge as to our Indian crops," if the experiments are conducted on private land. Such knowledge will be acquired by the department from the experiments themselves. It is unsatisfactory, after twenty years of experiment at Saidapet, to find the plea of want of knowledge put forward.

The only other condition precedent mentioned by Mr. Benson is "time sufficient to carry the experiments to some good end." Sufficient time will, of course, be allowed. The Government agree in the opinion that detailed information is not for present purposes required in regard to irrigation in Italy, Spain, &c.

As regards the selection of a suitable tract or suitable tracts of land, the Government resolve to direct that the Collectors of Kurnool, Godavari and Kistna be consulted. It is observed that in Kurnool and Cuddapah somewhat similar arrangements are now in force for the encouragement of irrigation, while in Godavari it is believed that the alteration of wet and dry crops on irrigated land is already practised to some extent.

The words we have italicised speak volumes. When referring to this subject a short time back, we took occasion to notice the extraordinary nature of this plea, and commented upon it in terms not flattering to those who had put it forward. We are therefore glad to see that the Government have marked their sense of this unsatisfactory plea of want of knowledge.

CAPTAIN CATANIA, of Dharur, in the Nizam's State, writing to the Agri-Horticultural Society of India in reference to Mr. Dumaine's paper on tussur silkworms, says :—

"I find I am greatly ahead of Mr. Dumaine in the domestication and propagation of the Tussur silkworm. I will send you a detailed account of my system of domestication at the end of the season. Mr. Dumaine speaks of gathering only *two* crops a year at Hazaribagh. We have *three* in the Deccan, and I cannot understand why there should be this difference, considering the worm is the same and the habits identical. In the same letter he says: Are you aware that the Cotton of *Cochlospermum Gossypium* is an article of commerce in Holland? Should you wish it, I will write and enquire the price it is sold at. I believe large quantities are sent to Amsterdam from Java. We have the tree by millions in our jungles, but hitherto it has not been utilized." Captain Catania has been asked for any additional information he may be able to furnish, together with a sample of the cotton to be obtained from Holland, if possible, to guard against mistakes.

.

The following is a summary of Messrs. William James and Henry Thompson's fortnightly circular of Indian Tea, dated London, 22nd October, 1885 :—

Since the 8th instant 49,000 packages have been brought to auction, including 2,200 from Ceylon and 500 of reprinted tea. At the early sales prices showed weakness and irregularity, but later on the tone improved, and prices closed last Thursday without change, except for common Pekoe Souchongs, which were $\frac{1}{2}$ d. cheaper. This week the feature has been the sustained demand at previous rates for tea "for price"—and at rather dearer prices for fine Pekoe Souchongs and Broken Teas. On the other hand, fine Assam Pekoes have not maintained their value, many sales showing $\frac{1}{2}$ d. to 2d. decline. The less active competition for Darjeeling teas must also be noticed, poor liquoring marks having receded very near to the low rates touched last season, when well-made Pekoes were selling at $\frac{1}{2}$ d. to $\frac{1}{4}$ d. per lb.; while some of the finer qualities are selling cheaper than they were a month ago. The shipments from Ceylon for the season ending 30th September were 3,800,000 lbs. Estimates of the next crop range between 6,000,000 and 7,000,000 lbs. The shipments from China at the end of September had reached a total of 116,000,000 lbs., as compared with 117,000,000 last season. The market is quiet, but the tone is steadier, with a hardening tendency for Congous under 7d. per lb.

.

A SHORT time back we noticed the result of the enquiries instituted in Burmah, as to whether salt formed an article of diet for cattle, and to what extent it was used by the Burmese in this respect. Our own opinion was that many of the diseases to which cattle are subject might be traced to the want of salt in their diet. The report of Mr. Cabaniss, the Assistant Director of Agriculture, British Burmah, on this subject, pointed to the craving for salt being a perfectly natural one in cattle. He said: "I have noticed the cattle fighting amongst themselves, to get at a salt-lick." The following, which we extract from the *Farmers' Review*, bears out the 'natural-craving' theory in reference to salt for cattle :—

Some writers recently have advanced the idea that the supply of salt to animals is wholly unnecessary, that the appetite for it in both animals and human beings is an artificially acquired one, and not a natural craving. But when the writer was enjoying his vacation a few weeks since on the Brule river in the Lake Superior country, his camp happened to be near a couple of natural salt-licks which were frequented by deer in such numbers that the ground was trodden by them like a barn yard in which a flock of sheep are kept. Now how did the wild deer in the woods acquire an artificial appetite for salt, or was their desire for it a natural craving, indicating a need of the physical system which salt alone will supply? To our mind very clearly the latter. The man who has the well-being of his live-stock at heart will see that they are supplied with salt to meet this craving of their nature. Pieces of rock salt to which they have access at all times is a better method of administering it, than to feed it to them in quantity at regular or irregular times.

DR. BONAVIA, of Etawah, has of late been making praiseworthy efforts to bring prominently to notice the valuable

medicinal properties of the *citrus*, or orange family. In a recent letter to the Agri-Horticultural Society of India, he says :—

"Allow me to bring to the notice of the Agricultural and Horticultural Society of India, the great importance of the genus *citrus* from a medicinal point of view. Dr. Maglieri, an Italian physician, had noticed that farm laborers in Italy used the decoction of lemon to recover from the cachexia left after ague, and he tried it himself with success. Dr. Lauchlan Aiken, of Rome, ~~Dr. Arriz~~ Dr. Maglieri's statement, and published the result in the *British Medical Journal* of 4th October 1884, page 659. Having a number of Malta lemons, which are identical with the Italian lemons, I thought it a good opportunity of making some experiments with them. I was struck with the medicinal powers of this decoction. It is a perfect remedy for the weakness and loss of appetite after ague: For uncomplicated cases of quotidian fever in the three cases I have tried it, it acted like quinine. For enlarged spleen of recent date, even when the spleen projects to an inch of the middle line of the abdomen, it is the best remedy I have yet tried. The above experiments were made with the lemon, but two other cases of weakness after fever, tried with the decoction of three fresh 'kaghzi nembos,' gave a similar result. I am now trying the large sour kind, which natives commonly call *khaat*. It would be worth while trying experiments with all kinds of sour oranges and lemons to ascertain whether all sour varieties of the genus *citrus* have this valuable medicinal property, or only some. In that case it would be worth knowing which variety possesses this quality. In a country like India, where ague, and weakness and cachexia after it, and also enlarged spleen are so common, this valuable property should, I think, be made widely known. Those who have tried the decoction of Malta lemon, and also that of 'kaghzi nembos,' say that the former has much the nicer flavour. This, though not of great, is of some importance. The way of making the decoction was pointed out in the *Pioneer* of 15th August last."

.

We learn from a home contemporary, that Mr. Charles Whitehead, in connection with the question then agitating farmers, viz., the increase of agricultural insect pests, intimated in May last to the Agricultural Department of the Privy Council that he was willing to prepare reports on insects injurious to hop plants, corn crops, fruit crops, and root crops. The Lords of the Council accepted Mr. Whitehead's offer, and he has now forwarded to the Council, and the department has published, the first report of the series—namely, that on insects injurious to hop plants. Mr. Whitehead states in his introduction that the risk of loss and destruction from injurious insects is increasing. The pests that mock the husbandman have long been known to be many and various. Mr. Whitehead gives several instances of new ones discovered of late years. The increase of insects follows *pari passu* the extension of culture, and the distribution of the plants which are special objects of their attacks. Insects are imported into England with agricultural produce, and they are also exported. It is a fortunate thing for us that the climate is fatal to some of the worst of agricultural pests, as, for example, the dreaded potato bug. To show how the insect nuisance is increasing, it may be mentioned that the hop aphid was unknown in America 25 years ago, and now it has become a serious trouble. Mr. Whitehead says that America has in revenge for the importation of this and other insects, retaliated by exportation into France of the phylloxera. Mr. Whitehead blames the wholesale and indiscriminate slaughter of insectivorous birds and animals. The hand of the farmer is and has been since Virgil's time against moles, and yet men wonder that wire-worms become more abundant each succeeding season. Mr. Whitehead specifies ten enemies of hops, and in each case he gives an account of the appearance of the insect, illustrated by a representation of the size, both natural and magnified, the mode of attack and results, the prevention and remedy. The hop, we find, is attacked by its own fly (*aphis humuli*), cone fly (*diolophus vulgaris*), wire-worm (*clater lineator*), jumper (*eucanthus interruptus*), flea (*haltia concinna*), and bug (*tygus umbellatorum*), as well as by the other moth (*hopialus humuli*), the red spider (*etrangopus telarius*), the strig miner (*pyllodes attenuatus*), and last, not least, an ugly creature—it is not to be scientifically classed as an insect, for it undergoes no transformation, and has only two stages of life—called the thousand

legs (*Julus Londonensis* or *Julus guttatus*). As a remedy for the attacks of this beast, Mr. Whitehead recommends the use of paraffin.

THE turmeric crop, which is a valuable one in certain districts in Southern India, has recently come up for consideration before the Madras Government with reference to the assessment to be charged for water supplied from irrigation canals to lands taken up for turmeric cultivation; it being alleged that, as the crop remains longer in the ground than other crops, including paddy, water has to be supplied over a more extended period, whereby the irrigation revenue suffers a very considerable loss, especially when it is considered that the rate of assessment is only half that charged for paddy, which is Rs. 4 per acre. It has therefore been recommended by a superintending engineer for irrigation that the crop should be assessed at Rs. 6 per acre. The matter was, however, referred to the Collectors of Godavari and Kistna, the latter of whom has furnished some particulars regarding the cultivation of turmeric which are interesting, and which we quote below. After defining the crop as a dry one, he says:—

It is reported to be put down in the end of July or beginning of August, and to be dug out by about March. During the first four months the rain, if copious, is sufficient; but if the season is bad, surface water is occasionally taken. During the remainder of the period surface water, if available, is occasionally taken, but never continuously. Turmeric is irrigated by channel irrigation, not more than three or four times a month, while a paddy crop is always under water several inches deep. Indeed, the turmeric roots are said to rot and die if the crop is allowed to remain under water without intermission. Turmeric, therefore, takes less water than a wet crop, but more than a dry one, and it is more valuable. There is no reason to treat turmeric as a double crop, as, unlike sugar-cane, betel, or plantains, it does not remain on the ground for the time required for two crops, and it is only occasionally (three or four times a month) and not continuously irrigated. Rs. 8 an acre therefore seems an excessive charge. The principal revenue officers in the deltas have been consulted on the question. The majority are of opinion that turmeric should be treated as a single wet crop and its irrigation charged for at Rs. 4 per acre, because of the length of time (eight months) it requires, the usual deduction being allowed for lifts. In this opinion I agree. This is stated by the Collector of Godavari to be the charge for turmeric irrigated by canal water in that district. The Tahsildars of Bandar and Gudivada would keep to the existing rate of Rs. 2, because turmeric does not require continuous irrigation.

The report of the Godavari Collector is substantially the same as the above. It has therefore been decided to fix the rate of assessment at Rs. 4 per acre.

MR. KENNEDY has contributed a very sensible article to a recent number of the *Calcutta Review*, entitled "Punjab ploughing." He says:—"Looking at the actual state of tillage in India, a scientific agriculturist will be, perhaps, inclined to think that the Indian peasant has made but little advance upon the primitive tillage which yokes a bullock to the branch of a tree for a plough and a thorn bush for a harrow, and with these rude appliances roughly scratches and harrows the soil. He may be inclined to think that, under British rule, agriculture alone of all the arts has not progressed, and still remains in the state it was before European skill and energy were brought to bear upon the industries of the East. But if we examine more closely into the subject and compare the efforts of the agriculturist with those of his ancestors, there may be found signs that the influence of scientific improvements has not been entirely unfelt. Too much must not be expected. In Europe, and especially in England, labour is dear, and every invention of machinery which can perform the work of men or horses, and every extension of the application of steam to drive such machinery proves effectual from the cheapness of fuel and the dearth of labour. But in India labour is still cheap, and labour-saving machines have not hitherto proved a success. Machines on the other hand, to increase the agricultural outturn, such as the Bihia Sugar Mill, oil-expressing machines, etc., have probably a great future before them. But until we thoroughly understand the condi-

tions under which native husbandry is carried on, the merits or demerits of the various operations of tillage the farmer practises, and of the various implements and tools he uses, and thoroughly understand the general principles which guide his practice—and such knowledge is still in its infancy—it would be unsafe to too rashly condemn his methods, or to ask him to forego the use of appliances which he understands, and of which others of which he is ignorant, and the advantages of which are still problematical." Of course, Mr. Kennedy does well to point out that improvements which work well in England may not do so in India, and should not, under the circumstances, be forced upon the acceptance of the native agriculturist, who is a bigoted conservative in his habits, and as a rule, quite innocent of education. Mr. Kennedy quotes an instructive instance of the results of the English system of ploughing on Indian lands, from the Punjab Famine Report, the writer of which was Mr. A. O. Hume, who says:—"I remember once seeing a practical English ploughman plough up a piece of land on the English system, that is, throwing the soil inland; the operation was beautifully performed, the crop germinated well, but when the time came for it to be watered, it naturally preferred to remain in the furrows between the land; the result was that the crop came to nothing. This system of ploughing in lands in England is employed on purpose to cause a surface drainage; in the Punjab we do all we can do keep moisture in the soil."

RESEARCHES ON SILK FIBRE.

THE silk industry at the present time is in a state of transition. It has attracted an unusual degree of attention in France, where efforts are being made for its development to the greatest possible extent. We have before called attention to the proceedings of the Lyons Chamber of Commerce, and the exertions of Mons. N. Rondot in this connection. We have now before us a small pamphlet containing the correspondence which has passed on this subject between the Secretary of State for India and Mr. Thomas Wardle, the well-known silk dyer of Leek, Staffordshire, who is well-known through his experiments in Indian dyes and tans, and his efforts for the improvement and utilization of Indian wild silks, and also as the author of a "Hand-book of the Wild Silks of India." Referring to a letter received by him from Mons. Rondot, Mr. Wardle remarks that "in what he says about muga, he only takes a practical view of the matter from the present smallness of the importation, but I am making some investigations in silk with beautiful samples which I have received from Mr. F. Stack, Director of Agriculture in Assam, and Mr. H. S. Darrah, Officiating Director of Agriculture in Assam, and which give promise of a great future for this silk, and I am hoping to point out to you before long, and to the Indian Exhibition to be held at South Kensington next year, proofs which will warrant the encouragement of the natives of Upper India to prosecute this industry to the extent of a very large exportation. I heartily join in Monsieur Rondot's wish that India should be awakened to the importance of the greatly growing Tussur industry, and it troubles me to think that the efforts I have taken in its initiation for the good of India should be seized by the quicker Chinese. Already, at Arrah, Mr. W. Peppe is engaged in improving the reeling of Tussur silk with remarkable success, leaving nothing to be desired from advice which I have from time to time given him, and it is quite as easy for the same to be done all over India. I am quite certain that every year will see a largely increased output of this silk, if it can be obtained. Last year the French bought 8,000 bales from Shanghai. Messrs. Brocklehurst and Sons of Macclesfield, alone, used 1,000 bales of raw Tussur silk last year, and that not reckoning the waste which they largely buy and use for spinning purposes."

What Mons. Rondot said on this subject in his letter to Mr. Wardle was as follows:—

The Tussur industry is now fairly launched at Lyons. It is no longer necessary to act in Europe in stimulating this industry, but in India. It is China which supplies us at the present time and some Chinese merchants at Chefoo conduct this trade with an activity which, I regret to say, has not been shown in India.

I have received from several merchants, or spinners of India, offers of service or sample skeins of Tussur raw, with requests for orders. As I am completely disinterested in these affairs, I have applied the manufacturers, through the Chamber of Commerce,

of these communications. You * Note by Mr. Wardle. may well think that we only made them laugh (*because of the backward state of reeling this silk*). From Ohefon I have received several packages of silk for trial. Some manufacturers have taken them, the first time at a rather low price, and at the present the relations are direct and active. You know that we have spun at Lyons some muga cocoons which Lord Lytton had caused to be sent to me, and which I sent to the Chamber of Commerce. We know this silk at Lyons well. But to tell the truth the muga interests nobody. One could not have 100 bales of this silk. Why occupy one's self with it? One can only obtain Tussur silk with difficulty. It is not doubtful that in some time this trade will be better known, and, for the moment, it is of the exportation from India that it is necessary to think.

The apathy shewn by India in regard to the Tussur silk industry, which M. Rondot noticed so forcibly, is a reproach to the country, and much to be regretted. India is the home of the Tussur worm. Efforts have, of course, been made to extend the cultivation of the Tussur, but these have been either by Government officials in isolated cases, or by amateurs. What little Tussur India does produce, is chiefly the product of cocoons collected by itinerant natives, who earn a precarious living by it. In some parts of India the industry has certainly assumed some pretensions; but taken as a whole, the Tussur industry in India is of very limited proportions indeed; and considering the demand which is being created for it in the European markets, it will be strange if some of our enterprising capitalists do not take advantage of the opportunity thus afforded them of making an effort to extend and develop an industry which has great possibilities before it.

At the ninth ordinary meeting of the Society of Arts, London, on 29th April 1885, Mr. Thomas Wardle read a most important and interesting paper on the "Researches of Silk Fibre," which we reproduce elsewhere in *extenso*. Mr. Wardle has gone minutely into the question, and we feel sure that his paper will be read out here with great interest.

At the same meeting, after the reading of Mr. Wardle's paper, the following interesting discussion took place:—

Mr. M. Blair (Glasgow) said he had recently had the opportunity of visiting India, and might say a few words about the wild silks of that country, to which he thought silk manufacturers in England had chiefly to look in the future. One of the first things which struck a visitor to India was the enormous resources of that great empire, the vegetable, animal and mineral, thoroughly explaining why it was that all the great nations which had held the East and West traffic had flourished so exceedingly—from the Babylonians and Phœnicians down to the English. The second thing, however, which struck him was the unreliable character of the people; the apathy and indifference to all ideas of improvement and advancement was something which an Englishman, and certainly which a Scotchman, could hardly comprehend. In India there was a large population living, and content to live, on the verge of starvation, and if you increased their income, one of two things took place. Either they worked half-time and so reduced their income to what it was before, or they added additional mouths to eat it up. Thus it was found that when rice was cheap, the work-people went away for half of the week, and left the machinery standing idle. This had an important bearing on the silk question. A vast quantity of silk material could be procured from India, but it would always be of poor quality unless it were prepared under European supervision. The silk was good, but it was not well reeled, and the people were too indifferent to improve it. The one thing needed for the resuscitation of the English silk trade was a large supply of cheap and good material, and for that they might look to India, not only from the *Bombyx mori*, but from other and indigenous kinds which Mr. Wardle had devoted so much time and study to; but it must be reeled better. He feared this would never be the case if they trusted only to the natives. Anything which required no very skilled labour, such as rice-growing, or perhaps cotton, they did very well, but where skill was required, they could not be depended on. If they had been trusted to grow tea, and prepare the leaves, there never would have been any Indian tea, worth speaking of, but under European supervision, this trade had grown enormously. The same policy should be

pursued with regard to silk, and the machinery should be, as far as possible, automatic.

Mr. Birchenough (Macclesfield) said good reeled silk was essential to the progress of the manufacture. He had not had much to do with tussur silk, but he could see a great future for it if it were well reeled. The whole country, and especially the silk trade, were much indebted to Mr. Wardle for his investigations.

Mr. Wells said Indian Tussur raw silk was practically unknown to the London trade, and asked if Mr. Wardle alluded to it. All to China, when he said that a large quantity was imported.

Mr. Wardle said he referred to China tussur from Shanghai.

Mr. Wally said he knew very little about silk, though he had done something to introduce new species of silkworm into Europe. He had lately seen carded silk from various species, such as Indian tussur, *Pernyi* from North China, and some from North America. He had sent specimens of these carded silks to the Paris Acclimatization Society. His main work had been the introduction of the insect, and he had no doubt that, this year, the Indian tussur *Mylitis* would be acclimatized in Spain, and perhaps in some parts of Italy, though it would hardly suit the northern parts of that country, as it would take three months to rear.

Mr. Ernest Hart said he knew nothing about silk, but as one of the general public he felt deeply interested in some of the facts stated in the paper. He was much struck with the fact that some silks largely sold here only contained one-seventh or one-eighth of pure silk; and that they were manufactured chiefly for the benefit of French manufacturers, though there was no doubt that England possessed special skill both in dyeing and weaving, and also acclimate peculiarly fitted for the treatment of silk. It was evident, therefore, that there must be some other element necessary for the restoration of the industry, and he gathered that that element was better technical education. If that were so, perhaps Mr. Wardle could tell them in what special direction their efforts should be turned; for he was evidently one of those men to whom this country owed so much, who added to indomitable energy and skill and industry, scientific tastes. He believed no industry could be considered in a hopeless state which had such men in its ranks.

The Chairman having proposed a hearty vote of thanks to Mr. Wardle, which was carried unanimously,

Mr. Wardle, in reply, after thanking the meeting for the compliment, said his principal feeling in this matter was one of anxiety and disappointment at the great loss which this country had sustained within the last thirty years by the gradual decay of the silk industry. It behoved every one who was anxious to regain it to set about the work at once. It was a melancholy fact, which could not be repeated too often, that for the last ten years the average value of manufactured silks imported into England from European countries had been twelve millions sterling, and he believed Mr. Birchenough would bear him out that if English manufacturers received orders for one-third that amount, it would make the silk centres of Coventry, Macclesfield, Congleton, Manchester, and Spitalfields very busy indeed. In reply to Mr. Hart's questions as to what he suggested, he would say, study carefully the report of the Commissioners on Technical Education, for if he understood it aright, it contained everything necessary to regain not only that, but any other artistic industry, either European or Eastern. It was a most valuable report, and he was sure it would do a great deal of good. It contained a vast amount of information, and the deductions which the Commissioners had drawn from their travels and observations were such as would enable any energetic person in time to overcome any difficulties. Mr. Wardle concluded by drawing attention to and describing the various specimens of silk exhibited.

The Chairman remarked that the particular researches of which Mr. Wardle had given some account, were undertaken at the instance of the Chamber of Commerce of Lyons, and had been followed by that body with the greatest interest. Although there were already excellent technical schools at Lyons, a special laboratory had been added in consequence of these researches. He drew special attention to this fact, because it was one of those significant things which showed the difference between the mode of operations here and abroad. We always had able and enterprising manufacturers, but they were left to their own unaided efforts, stimulated by competition; whereas, abroad, those who had a common interest were banded together in a strong organization which co-operated for the welfare and advancement of their particular industry. Such was the case at Lyons and elsewhere. In every industrial centre in England there was a need for the same kind of thing, and if they could ever hope to recover the

- industries; it must be by imitating the commercial spirit shown by our competitors abroad. He knew that many felt this difficulty and until they could bring to bear not merely individual enterprise and generosity, which was undoubted, but also something like the aid of public funds wisely administered, for the promotion of that which was known and acknowledged to be the greatest public good, they would fall in competition with our, in so many respects, wiser, and in many respects more successful, competitors on the Continent.

GAMBOGE.

The Government of India have been instituting enquiries into the indigenous production of gamboge in certain parts of India, and into the cost of its collection. It has been ascertained that the tree grows pretty freely in the Madras presidency. From a report by the Collector of Malabar to the Board of Revenue, we learn that there are four species of *Garcinia* indigenous to the forests of this district. They are:—

(1) *Garcinia morella*, which grows on the Peria ghat in the extreme north-west portion of the Wynad taluk up to an elevation of about 1,500 feet. This species yields the tree gamboge of commerce. There is a considerable export from Ceylon, but none from the district.

(2) *Garcinia pictoria*.—This is widely distributed, and is found growing along the slopes of the Western Ghats, from 1,000 to 2,000 feet elevation. It is very abundant in the Chenai Nair forests, and fairly common everywhere. It yields an excellent pigment, samples of which were sent to the International Forestry Exhibition, Edinburgh, last year; also to the Calcutta Exhibition. The gamboge is collected by lightly scraping the moss and the old bark off the stems of the trees, and then pricking them all over, with an instrument resembling a hair-brush, with wire nails fixed in it at intervals of $\frac{1}{2}$ inch apart. The work should be done from December to March, when there is no rain. The gamboge collects in little tears, about the size of a small pea, in from three to four days, and is quite hard in a week, when it can be collected. The cost of collection amounts to about Rs. 1-8-0 per pound, which is as much as the product is worth in the London market; hence there is no trade in it here.

The Collector says that a second way of collecting the gamboge is to clean the bark of the trees of all extraneous matter, and then to strip it off, pound and boil it. A yellow extract is thus obtained, which, when inspissated yields a golden brown gamboge of inferior quality, worth about 6d. a pound. The stripping of the bark, of course, kills the tree. The method is therefore a wasteful and expensive one. The fruit of both species are rich in gamboge, and the seeds yield an oil.

(3) *Xanthochymus pictorius*.—This species is indigenous to the ghat forests above Karimpoya in Nilambur. It bears a large golden-colored, thin-skinned edible fruit of a pleasant sub-acid flavor, in bunches of 3 or 4 together. It is cultivated at Calicut and in the Wynad, and is a tree of exceedingly slow growth. The gamboge yielded by it is resinous, and worthless as a pigment.

(4) *Garcinia cambogia*.—A very common tree on the Western Ghats, up to 4,500 feet, where, however, it rarely exceeds 20 feet in height. It yields a translucent resinous gamboge useless as a pigment. The fruit is ribbed, and of a bright canary color. The aril is edible, being of a pleasant sub-acid like the mangosteen. The rind of the fruit, when green, is intensely acid, and is used by the Kurumbers and other wild tribes as a substitute for tamarind in their curries. The seeds yield an oil.

(5) *Garcinia purpurea*.—A very rare tree on the ghats, but cultivated at Calicut for the sake of its edible fruit, which is of a bright purple color. It yields a gamboge which might be used as a pigment.

Garcinia Travancorica et *Wightii* are both said to yield excellent pigments, but they do not occur in this district.

The Collector of Nilgherries says that *Garcinia pictoria* does not grow in any part of the district, and that no trade is carried on in gamboge yielded by this tree. The Collector of Sea Customs, Madras, who was requested to furnish particulars of the exports and imports of the product, states that there was no trade in it during the last two years. It

would thus appear that, although the tree yielding the gamboge of commerce exists in an indigenous state in parts of India, it is found that it cannot be gathered at a cost sufficiently low to render it a remunerative industry. This seems strange when the cheapness of labour in India is taken into consideration. It is clear that there must be some defect in the mode of collection; for how else can it be explained that Ceylon can export the product at a profit to those who collect it in the island? Further enquiry is needed to prove beyond doubt that the development of the industry cannot be rendered profitable.

The source of the Ceylon gamboge is the *Cambogia gutta*, also known as the *Hebradendron Cambogioides*. This is probably the variety named by the Collector of Malabar as *Garcinia Cambogia*. The Siam gamboge is said to be the product of *Garcinia Cochinchinensis*. Another variety, *Garcinia elliptica*, found in Sylhet and Tavoy, also yields a kind of gamboge. The *Garcinia mangostana*, a native of Malacca, yields that splendid fruit called mangosteen. The entire order to which the *Garcinia* belong—*Clusaceae*, are natives of hot, humid regions in the tropics, and many of the genus are found in South America.

RAIL-BORNE TRAFFIC, CENTRAL PROVINCES, 1884-85.

The returns of the railway-borne traffic of the Central Provinces, for the official year ending 31st March 1885, have just been issued. The railway stations have been divided into five blocks, grouped as follows:—

- (1) *Jubbulpore*, including all stations in the Jubbulpore district.
- (2) *Nerbudda*, including all stations in the Narsingpore and Hoshungabad district.
- (3) *Nimar*, including all stations in that district.
- (4) *Nagpore*, including all stations in the Wardha, Nagpore, Chanda, and Bhandara districts.
- (5) *Chattisgarh*, including all stations in the Rajpore district.

The only difference observable in the classification of headings, from the system hitherto in vogue, is the omission in the present report of 'treasure,' which has resulted in an enormous decrease in the calculated value of the traffic. The total traffic of the year, in so far as imports are concerned, shows a large decrease on the previous twelve months. The figures are—

1882-83.	1883-84.	1884-85.
<i>Maunder.</i>	<i>Maunder.</i>	<i>Maunder.</i>
34,95,230	42,59,666	86,07,974

The value of these, in rupees, was for the three years respectively—

Rs.	Rs.	Rs.
3,13,47,350	3,00,91,000	2,86,52,722

It will thus be seen that whereas in *weight* the figures, besides being very much less than for the previous year, are in excess of those for 1882-83, in *value* they show a large falling off. But it is pointed out that the figures for 1882-83 are not strictly comparable with those of the following years, as they were collected on a different system. The differences resulting from this alteration in the system of registration, are not however believed to affect the totals to any very great extent. The figures above show a decrease of 16 per cent in the amount, and 27 per cent in the value of the imports. The exports for the past three years were—

	<i>Weight in Maunder.</i>	
1882-83.	1883-84.	1884-85.
1,28,08,708	1,68,34,850	1,82,74,720
	<i>Value in Rupees.</i>	
4,19,53,746	5,45,03,013	3,96,65,493

There was thus an increase of 9 per cent in the amount, but a decrease of 28 per cent in the value of the exports. It is explained that this result is due to the non-registration of 'treasure,' as above noted, and to the rectification of what appears to have been a mistake in the traffic returns of the previous year under "intoxicating drugs." The first of these reasons is also assigned for the decline in the value of imports. The principal items of import were coal, cotton-twist, yarn and piece-goods, gunny-bags, metals, salt, sugar, and tobacco. The figures show a great decrease in coal, and an appreciable falling off in cotton piece-goods, gunny-bags, undrained sugar, and tobacco. An increase, on the other hand, is noticeable in cotton;

twist and yarn, metals other than iron, and drained sugar. The principal items of the traffic may be contrasted as follows:—

	QUANTITY.		VALUE.	
	1883-84.	1884-85.	1883-84.	1884-85.
Coal	10,72,744	12,90,886	8,22,123	8,89,951
Cotton	1,12,865	72,728	10,92,975	10,77,209
Wheat	77,08,223	97,51,180	1,54,18,448	1,46,88,095
Rice	10,68,806	12,83,019	80,05,088	28,00,604
Other Grains	15,19,706	11,88,774	25,76,006	17,86,918
Hides	26,888	67,139	5,04,886	9,06,376
Linseed	20,99,558	25,11,181	65,61,119	73,76,594
Tilseed	9,92,075	2,60,761	84,41,448	9,94,227
Myrabolans	...	2,24,193	...	5,74,435
Stick Lac	73,729	67,282	9,58,477	12,11,078
Ghee	28,723	26,630	6,02,323	7,91,876

Nearly the whole of the coal was the yield of the Warora mines. Cotton has not been so low for many years past. The increase in the quantity of wheat is the largest on record, and is the produce of nearly 1,400,000 acres, or 41 per cent of the entire recorded wheat area of the provinces. The decrease in value is due to prices having come down very low, viz., from Rs. 2 per maund in 1883-84, to Rs. 1-8. The whole of the wheat, practically, was consigned to Bombay. The increase in the export of linseed is remarkable; it is chiefly the produce of the Chhattighurh block. Myrabolans were registered separately for the first time. The trade is of comparatively recent origin, but has before it great possibilities; and as the trees which bear the fruit (*Terminalia Myrabolana*, *chebulu*, and *bellerica*) are found growing abundantly in the provinces, it promises to become a most productive source of forest income. It may be mentioned that Calcutta had a very small share in the traffic with the Central Provinces, almost the whole of the traffic having been done with Bombay. In comparing the exports per 1,000 acres under crop, it is found that linseed comes first, then wheat, and thirdly, rice. Our space necessarily compels us to notice the report only in the briefest possible manner. As a rule, trade returns consist chiefly of long rows of figures, that do not form very entertaining reading, but the report under reference is, however, an exception. It is comprehensive without being tedious, and Mr. Fuller has succeeded in investing it with a degree of interest that is unusual in such compilations.

Miscellaneous Items.

A CORRESPONDENT writing to one of our German exchanges says that the Flax Commission at Lille a short time ago invited the chief German, English, Belgian, and French spinners to Antwerp, in order to agree upon common conditions for the business in Russian flax, and to adopt an international convention. The Germans intimated their approval of the plan at once by telegraph, and the meeting of English, French, and Belgian spinners at Antwerp adopted the scheme with a few modifications, appointing an international committee of eight members to further the interests of spinners.

Kuhlow's says—At present Hamburg ranks as the first petroleum port of the Continent. It is interesting to observe the increase of the petroleum imports there, as shown by recent statistics. The first consignment of petroleum was received in 1860, now 25 years ago. The imports were the next year 3,210 centners, in value 53,950 marks, and in 1871 the value of the imports was 15 million marks, and in 1884 it had reached the enormous sum of 28 million marks. In the first years the average price of petroleum was 28 marks per centner, and latterly only 8-15 marks. These figures illustrate the extraordinary distribution of this article of trade.

It is calculated that the total production of sewing machines in all the industrial States of the earth is 1,500,000, of which a good third fall to German manufactories. If the population of the earth is taken as 1,400 millions, it is found that every year one machine is made for every 930 people, though as a matter of fact, deducting for uncivilized nations, the population amongst which this trade is carried on is only some 600 millions, so that this would be one machine for every 230 civilized persons. In Germany, however, from 150 to 200 persons may be reckoned to a machine. America is the home of the modern sewing-machine, but German skill has succeeded in surpassing the American article in capability and efficiency of work.

THERE are four candidates in the field for the appointment of Superintendent of the Stud Farm and Remount Agent, Hyderabad, viz., Major Gough; Mr. Stevens, private secretary to the Nawab Khورشid Jah; Mr. Wilkinson, in the employment of the Nawab Vikar-ul-Omrah, and Captain Hayes, of horse-breaking fame. The Stud Farm was established by the late Minister in 1877 for the purpose of breeding horses and cattle, and for the cultivation of grass and fodder. A few stallions are kept at Rajampett, while some thirty or forty others are placed for breeding purposes in various parts in the districts. Since the introduction of proper stud arrangements, the number of horses brought for sale to the Mallegauz fair increased from a few hundred to nearly four thousand.

The imports into Kurrachee during the first half of the current official year amounted in value to over a crore of rupees; the total for the same period of 1884 being only a little more than three-quarters of a crore. The value of the exports from Kurrachee, during the first six months of this year, amounted to over two crores, against less than one and three-quarters crores for the same months of 1884. With regard to exports, it appears there has been a large increase under the heads of wheat, cotton, gingelly seed, and hides. There has been a falling off in the exports of rape seed, owing to the poorness of the European markets; there being large stocks both at Kurrachee and up-country, which dealers are reluctant to sell at a loss. It is believed that the exports of wheat will be much larger this month and in December, than in the same months of 1884. According to trustworthy information, there is now in Kurrachee, in the hands of native sellers and exporting firms, fully 1,200,000 cwt. of wheat; to say nothing of further quantities that may come in from up-country, to complete sales already made.

Selections.

RESEARCHES ON SILK FIBRE.

By THOMAS WARDLE, F.C.S., F.G.S.

THE Chamber of Commerce of Lyons having done me the honour to request me to conduct an examination of the fibres of the various species and varieties of silk, both those obtained from domesticated worms and wild or semi-wild ones, on the basis of my former researches, partly described in my "Hand-book of the Wild Silks of India." I have, for the past twelve months, given a more thorough examination of these fibres, from cocoons in my own possession, as well as from cocoons furnished to me by the Lyons Chamber, and Monsieur Rondot, an influential member of the Chamber, and ex-president of the silk section of the International Exhibition of Paris, 1878, whose able time and energies are given to the nurture and development of the French silk industry. The President of this important and influential Chamber has, in several letters to me, expressed his high opinion of the value and importance of these continued investigations, the consequence of which is that, at Lyons, a laboratory is being constructed, called Laboratoire de Sericulture, and an earnest sericulturist, Monsieur Dusuzau, has been appointed curator, whose office and work it will be to record the results of examination of the various races of silk, methodically and regularly.

The effect of this annual and scientific work on the silk fibre will be to give, by a closer insight and more extended knowledge, a direction in the better reeling and sizing of silk, both European and Eastern, in the earlier stages of manufacture. The production of a thread of raw silk as regular and uniform as possible, is still a desideratum, particularly in China, where the raws have mostly become very irregular and badly sized, probably through price, competition, and decrease of sufficiently skilled reeling labor. In India, too, there is great need of improvement and renewed stimulus in this respect; for although much was done years ago to improve the reeling of Bengal silks, the effort has not been continuous enough. Much remains to be done, for I think if India silk could be well reeled generally, it is from that continent we ought to look for a great supply. In the wild silks of India, it is simply the coming want, and the application of improved reeling appliances will mark a new era in the utilization of tussur and several other species of wild silks, a utilization which is already one of the most remarkable facts in sericulture, and which may be said to take its date practically in 1876, when the amelioration and capabilities of these wild silks were first announced and shown by me in the Indian section of Paris Exhibition of that year, under the direct supervision of H.R.H. the Prince of Wales, and of the energetic efforts of Sir Philip Goultie Owen, with such success as gained from the jury the highest award—the diploma of honour for the Viceroy of India.

It might be naturally enough supposed that in a continuous thread or hove of silk, as unwound from the cocoon, an absolute regularity of fibre would not be found; such is indeed the case, and my investigations have had for their objects the recording of these differences throughout the entire length of the cocoon thread, both as to diameter or thickness of fibre, strength, and texture, or elasticity of various species of silk, including the silk of commerce, produced by the *Bombyx mori*, or mulberry-fed worm, also various wild

silks, and some spider silks. These points have been recorded at intervals of fifty metres, and the following tables show the results. All species of silkworms have two stores of silk, one on each side of the alimentary canal; and below their mouths they have two so-called apertures or orifices, to which I have ventured to give the name of "seripositors," through which the silk issues simultaneously in pairs of fine parallel filaments or fibres, forming in fact a double thread. For all practical purposes I have considered it sufficient, in estimating the tensions, strengths, and diameters, to give those of this double thread; as in reeling the silk from the cocoons into skeins, it is, of course, invariably drawn off in the form of a double thread, although so fine is it as to be apparently one.

The French term for this double thread, is "bave," and each of the single fibres composing it is called "brin," which is synonymous with our word "fibre."

The method by which I have reeled the bave or double thread from the cocoons is as follows:—The cocoons were first softened by keeping them immersed for several hours in a dilute aqueous solution of Marseilles soap, which, before it was used, was examined and found to be free from any appreciable excess of alkali, and then raising the temperature of this liquid for a few minutes to about 120° F. When the cocoons were soft enough, the short or waste fibres were pulled off the outside of them until the end of the double reelable thread or bave was found. This was attached to the machine, a drawing of which is on the table, and the thread reeled, the cocoon remaining floating on the surface of the soap solution in which it was softened until nothing was left, except an unwindable and extremely thin shell of silk immediately surrounding the chrysalis. The machine also registers the length of bave reeled.

I have preferred to examine and to register the two fibres composing the bave conjointly because—

1st. I thus get all the results which would be obtained by examining them singly, as whether the tension is estimated with either a single or a double thread the same mean or average must be obtained, and by finding the average strength and diameter of the double fibre, and dividing these by two, the average strength and diameter of the single fibre can be, of course, easily ascertained.

2nd. I find it somewhat difficult and very tedious to separate the two threads by any convenient solution, and I think there is risk of mechanical injury to the fibres, which would seriously affect the results.

In estimating the tension of the bave, I cannot distinguish that one fibre breaks before the other, but both appear to break at the same time, although the fibres of several species of wild silks being almost flat and joined together in pairs by their edges are not so strongly united as, and separate more easily than, the round fibres of mulberry silk; and in estimating the tension of the bave of these silks, it must of course be first ascertained that the two fibres have not become separated.

After each cocoon was reeled into a skein, I began to unwind the double thread from the machine, commencing at the inner end, that is, the end that was nearest the chrysalis, taking the first five metres for examination. I then unwound fifty metres, which I threw away, and took the next five metres for examination; and I went on thus until I arrived within five metres of the other or outer end of the reeled thread, which five metres I always examined, although the length of bave between this and the preceding five metres examined might be less than fifty metres. The bave, or double thread, of each cocoon was therefore tested for its strength, tension, and diameter, at every fifty metres of its length, except at its outer end.

Silk is well known to possess considerable elasticity. I have endeavoured to estimate this elasticity or tension by attaching three decimetres of the bave at a fixed point, on a scale divided into centimetres and millimetres, and then stretching it until it broke, and noting the point on the scale at which the breakage occurred.

The strength of the bave was ascertained by a serimetre, contrived in a homely manner, consisting of a spring balance with a scale divided into drams and sixths of drams avoirdupois. Fifteen centimetres of the bave were attached to the balance arm and gradually pulled until breakage occurred, the points of its occurrence remaining registered on the scale of the balance.

The diameter of the bave was measured under the microscope with a power of 250 diameters, with the aid of an eye-piece micrometre, seven of the divisions on which represented 1/1000 inch.

Between thirty and forty cocoons of different kinds formed the subject of this examination. Amongst the mulberry silks are several breeds or "races" from the various silkworm districts of the south of France, several from Japanese and Chinese seed, but reared in France and Switzerland, also Italian and Graecoan, as well as cocoons from Japan and China. The list also includes the following wild silks:—The Indian *Tussur*, the Chinese *Perny*, the Japanese *Yamamai*, as well as *Muga* silk, *Attacus Cynthia*, and *Attacus ricini*, and *Lasiocampa otus*. Their peculiarities, structure, and properties are fully described in the tables which follow.

Next in order is arranged a very interesting series of spider silks of the following species:—

1. An *Epeirid*, *Nephylengis malabarensis* (Watch), an Indian spider sent to me for examination by Professor Threlton Dyer.

The following five have been sent to me by the eminent authority on spiders, the Rev. O. P. Cambridge, of Bloxworth Rectory, Wareham:—

2. *Nephila plumipes* (Koch), United States, America.
3. Egg cocoons of an *Epeirid* sp., Adelsburg.
4. Silk from the nest of *Proctea durenii* (Walck), from Palestine.
5. Egg cocoons of *Metea menardi* (Latr.), Devonshire.

6. Egg cocoons of *Vanina maculata* (Kays), N. Corrientes, La Plata.

7. A supposed spider silk, dyed red in South America, lately sent to me for examination by Messrs. Marshall and French of London.

1. *Three pale yellow Cocoons, rare Bione (Drame) Nyons.*

Not very readily reelable, and a rather large quantity of waste on the surface of the cocoon. Internal unreliable shell surrounding the chrysalis extremely slight and transparent. The silk on the outside of the cocoon is almost white, but becomes gradually yellow, as the interior of the cocoon is approached. The most internal part of the reelable fibre is quite bright yellow. Length of cocoon before reeling, 1½ inches. Diameter, ¼ inch. Length of double fibre reeled, 265 metres.

The averages of six estimations of the tension of the bave, at each distance tried, throughout the cocoon, were as follows:—The figures represent the number of centimetres which three decimetres of the double fibre will stretch or extend before it breaks:—

Inner end.	At 55 metres.	At 110 metres.	At 165 metres.
3.2	3.7	3.3	4.2
	At 220 metres.	Outside end.	
	3.4	4.7	

The averages of six estimations of the strength of the bave or double thread at each distance tried, throughout the cocoon, were as follows:—The figures represent the number of drams avoirdupois which fifteen centimetres of the double fibre will support before breaking.

Inner end.	At 55 metres.	At 110 metres.	At 165 metres.
3½	4 4/8	5½	4
	At 220 metres.	Outside end.	
	4½	4½	

The averages of six estimations of the diameter of the bave or double thread of each distance tried throughout the cocoon were as follows:—The figures represent the diameter in fractions of an inch:—

Inner end.	At 55 metres.	At 110 metres.	At 165 metres.
1/810	1/790	1/775	1/900
	At 220 metres.	Outside end.	
	1/890	1/920	

2. *White Cocoon, race Japan; Grisons, Suisse; harvest of 1884.*

This cocoon reeled tolerably well, but had on its surface a rather large amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was moderately thin. Length of cocoon before reeling, 1½ inches; width 5 inches. The length of the double fibre reeled was 270 metres.

3. *White Cocoon from Kalamata, Morea, Greece; crop of 1884.*

This cocoon reeled tolerably well, having on its surface a moderate amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was moderately thin. The silk throughout the cocoon was white, like China silk. Length of cocoon before reeling, 1½ inches; width 8 inches. The length of the double fibre reeled was 360 metres.

4. *Green Cocoon from Japan; Grisons, Suisse; crop of 1884.*

This cocoon reeled tolerably well, having on its surface a moderate amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was about the usual thickness of that of mulberry silk cocoons. Length of cocoon before reeling, 1½ inches; width 8 inch. The length of the double fibre reeled was 320 metres.

5. *Cocoon of Mulberry Silk, China.*

This cocoon reeled very easily, having on its surface only a moderate amount of waste unreelable fibres. The external unreelable shell of silk surrounding the chrysalis was very thin and transparent. The silk throughout the cocoon was very white. Length of the cocoon before reeling, 8 inch. Width 8 inch. Length of double fibre reeled, 476 metres.

6. *White Cocoon from Bagdad, Turkey in Asia.*

Reeled tolerably well, having on surface a moderate amount of waste unreelable fibres. Internal unreelable shell of silk surrounding the chrysalis about the usual thickness of that of the mulberry silk cocoon. Length of cocoon before reeling, about 1½ inches. Width 8 inches. Length of double fibre reeled, about 640 metres.

7. *Yellow Cocoon from Ronda, province of Granada, Spain.*

Reeled tolerably well, having on surface a moderate amount of waste unreelable fibres. Internal unreelable shell of silk surrounding the chrysalis about the usual thickness of that of mulberry silk cocoons. Length of cocoon, before reeling, about 1½ inches. Width, 11/16. Length of double fibre reeled, about 335 metres.

8. *White Cocoons from Granada, Spain.*

Reeled very well, having on surface a moderate amount of waste or unreelable fibres, and the internal unreelable shell surrounding the chrysalis about the usual thickness of that of the mulberry silk cocoon. Length of cocoon before reeling, 1½ inches. Width, 8 inch. Length of double fibre reeled, 376 metres.

9. *White Cocoon of Italian-green Noy.*

Reeled exceedingly well, having on surface a tolerable amount of waste unreelable fibres. Internal unreelable shell of silk surrounding the chrysalis about the usual thickness of that of the mulberry silk cocoons. Length of cocoon before reeling about 1½ inches. Width, 8 inch. Length of double fibre reeled, about 620 metres.

10. *White bivoltine Cocoons from Japan, bred at Montpellier.*

Easily windable, but a rather large quantity of waste on the surface of cocoons. Internal unreelable shell surrounding chrysalis extremely slight and transparent. Silk throughout cocoon very white. Length of cocoon before reeling $1\frac{1}{2}$ inches, and diameter $\frac{1}{4}$ inch. Length of double fibre reeled, 316 metres.

11. *White Cocoons from Corea, Greece, bred at Montpellier.*

Reeled exceedingly well, having on surface only a very slight amount of waste or unreelable fibres, and the internal unreelable shell surrounding the chrysalis being extremely slight and transparent. Silk throughout the cocoon very white. Silky walls of cocoon considerably thicker than usual, as shown by the greater length of fibre reeled, as well as by section. Length of cocoon before reeling, 1 inch; width, $\frac{1}{4}$ inch. Length of double fibre reeled, 479 metres.

12. *Yellow Cocoon of a bivoltine race, from Tonkin.*

Reeled well. Had on surface a moderate amount of waste unreelable fibres; and the internal unreelable shell surrounding the chrysalis about the usual thickness of the mulberry silk cocoons. Length of cocoon before reeling, about $1\frac{7}{16}$ inches. Width $9/16$ inch. Length of double fibre reeled, about 200 metres.

13. *Pale yellow Cocoons, from Morristol, France.*

Reeled tolerably well, having on surface a moderate amount of waste unreelable fibres. Internal unreelable shell of silk surrounding the chrysalis about the usual thickness of that of the mulberry silk cocoon. Length of cocoon, before reeling, $1\frac{7}{16}$ inch. Width $11/16$ inch. Length of double fibre reeled, about 425 metres.

14. *White Cocoons of a species from Shanghai, China, bred at Monplaisir, Lyons.*

Reeled exceedingly well, having on its surface only a very slight amount of waste or unreelable fibres, and the internal unreelable shell surrounding the chrysalis being extremely slight and transparent. Silk throughout the cocoon very white. Length of cocoon before reeling 1 inch, and diameter about $\frac{1}{4}$ inch. Length of the double fibre reeled, 308 metres.

15. *White Cocoon from Valleranque (Gard), France.*

Reeled exceedingly well, having on its surface only a very slight amount of waste or unreelable fibres and the internal unreelable shell surrounding the chrysalis being extremely slight and transparent. The cocoon, before reeling, $1\frac{1}{2}$ inches, and diameter $\frac{1}{4}$ inch. Length of the double fibre reeled, 640 metres.

16. *Cocoons from Pihang Chiao ts' an silkworm, China; race, domestic and bivoltine.*

The fibres of this cocoon are very regular in diameter, the have being $1/1175$ inch, and the single fibre $1/1750$ inch. The silk is light yellow throughout the cocoon.

17. *Pat-jai ts' an. White cocoon, China; race, domestic.*

The have of this cocoon has an average diameter of $1/925$ inch, and the single fibre $1/1650$ inch. The diameter varies only within narrow limits throughout the have.

18. *White Cocoon; race, Sina, bred at Nyons (Drome).*

The have of this cocoon has an average diameter of $1/715$ inch, and the single fibre $1/1430$ inch. The diameter varies only within narrow limits throughout the have.

WILD SILK.

19. *Cocoon of Tusser Silk (Antheraea mylitta), written also Tassar, Tussore, Tussah, Tussar, from Outlack.*

This cocoon reeled moderately well, but had on its surface a somewhat considerable amount of waste or unreelable fibres, but the internal unreelable shell surrounding the chrysalis was thin and transparent. Silk throughout the cocoon of the usual fawn colour of tusser silk. Length of cocoon (without pedicel) before reeling, $1\frac{1}{2}$ inches. Width, $\frac{1}{4}$ inches. Length of double fibre reeled, 426 metres.

20. *Cocoon of Antheraea Pernyi, China, the so-called Tusser silk of China.*

This cocoon reeled tolerably well, having on its surface a moderate amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was moderately thin. The silk throughout the cocoon was of the usual fawn colour of tusser and most of the other Indian wild silks. Length of the cocoon before reeling, $1\frac{1}{2}$ inches. Width, $\frac{1}{4}$ inch. Length of double fibre reeled, 492 metres.

21. *Cocoon of Attacus Ricini, or Eria Silkworm.*

This cocoon was extremely difficult to reel, and had on its surface a considerable amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was moderately thin. The silk throughout the cocoon was white, some cocoons being rust colour. Length of the cocoon before reeling $1\frac{1}{2}$ inches. Width, $\frac{1}{4}$ inch. Length of double fibre reeled, 320 metres.

22. *Cocoon of Antheraea Assama, or Muga Silkworm.*

This cocoon reeled tolerably well, having on its surface a moderate amount of waste unreelable fibre. The internal unreelable shell of silk surrounding the chrysalis was moderately thin. The silk throughout the cocoon was the usual fawn colour of tusser and other wild silks of India. Length of the cocoon before reeling $1\frac{1}{2}$ inches. Width, $\frac{1}{4}$ inch. Length of double fibre reeled, 370 metres.

23. *Cocoon of Antheraea Yama-nai, Japan.*

This cocoon reeled tolerably well, and had on its surface only a moderate amount of waste unreelable fibres. The internal unreelable shell of silk surrounding the chrysalis was thin and transparent. The silk throughout the cocoon is very beautiful and lustrous,

being of a light yellowish green colour, whilst the superficial layer of the cocoon is bright green. Length of the cocoon before reeling, $1\frac{1}{2}$ inches. Width, $\frac{1}{4}$ inch. Length of double fibre reeled, 480 metres.

24. *Cocoon of Attacus Cynthia, Algeria.*

This cocoon was rather difficult to reel, and had on its surface a somewhat considerable amount of waste or unreelable fibres, and the internal unreelable shell of silk surrounding the chrysalis was not so thin as in the tusser cocoon. Silk throughout the cocoon of the usual fawn colour of tusser and other wild silks. Length of cocoon before reeling, 2 inches. Width at widest part, $\frac{1}{4}$ inch. Length of double fibre reeled, 280 metres.

25. *Cocoon of Antheraea Frithii.*

This cocoon being pierced by the bit of the moth could not be properly reeled, but I have determined the tension, strength, and diameter of the fibres in two different parts of the cocoon, with the following results:—

Tension.		
Inner end.		Outside end.
74		88.
Strength.		
Inner end.		Outside end.
19		94/5.
Diameter.		
Inner end.		Outside end.
1		1
358		363

In this cocoon, the two fibres of which the have is composed, had a great tendency to separate, and did not adhere together as in mulberry silk cocoons.

26. *Burre, or waste silk, from two reticulated cocoons of Caligula Japonica. One red, the other light grey.*

These fibres run in pairs. They are flat and united together by their edges. They are not marked with longitudinal striae, like tusser silk fibres. They have an exceptionally large diameter, the red one measuring $1/380$ inch for its single fibre and $1/165$ inch for its have, and the other light grey one $1/310$ inch for its single fibre, and $1/155$ inch for its have. These figures show the average diameters, the variations not being unusually great.

27. *Cocoons of Sai yen ts' an; from a new kind of wild silkworm feeding on the mulberry leaf.*

The fibres of these extremely small cocoons are round, run in pairs to form the have, and have all the essential characters of mulberry silk. They are, however, much finer than the fibres of the silks of commerce, the diameter of the have being $1/1400$ inch, and of the single fibre $1/2800$ inch. This diameter is very uniform throughout the cocoons. The colour of the cocoons and silk is very little different from that of tusser.

28. *Lastocampa otus; 1 cocoon.*

This cocoon was so very much damaged when I received it, that it was impossible to reel it. I have measured the diameter of a few fibres taken from it at random, with the following results. The figures represent the diameters in fractions of an inch:—

$\frac{1}{2000}$	$\frac{1}{2000}$	$\frac{1}{2000}$	$\frac{1}{2000}$	$\frac{1}{2900}$	$\frac{1}{2800}$
2000	2000	2000	2000	2900	2800

Average of single fibre, $1/2150$; double $1/1075$.

The fibres were all white, and the cocoon measured in length $2\frac{1}{2}$ inches, and in width, $1\frac{1}{2}$ inches.

Before proceeding with the spider-silk, it will be well to mention the outcome of these examinations.

First, as to the tension. It is clearly proved that the tension varies in proportion to the strength and thickness of the have, being less at the thinner ends of the have than at the thick middle portions. In the *Bombax mori* silks (the mulberry-fed worm silks), the difference in tension between the thinnest parts and the thickest is; in many cases, 1'0 to 2'0 centimetres, and often more, in three decimetres of the have, that is, a metre of the thinnest parts of the have would stretch, say 12'0 centimetres, whilst at the thickest parts it could be extended 15'0 to 18'0 centimetres, or more, before breaking; and the same proportion between tension and thickness obtains throughout the varying tension of the whole of the have of each cocoon.

The strength, as might be expected, varies in the same proportion as the tension, the thinnest parts of the have, roughly speaking, breaking with a weight of 3 to 5 drams, and the thickest parts, with a weight of 5 to 8 drams.

Coming to the most important feature of the have, it will be interesting to show in which way the thread varies in size or thickness; or, as I have previously termed it, diameter. The transverse section of the thinnest parts of the have (the double thread be it remembered), again speaking roughly, measures $1/3000$ inch to $1/1000$ inch, whilst at the thickest parts its measurement is $1/700$ inch to $1/800$ inch. The six or eight trials along the entire length of the cocoon thread, as a general rule, show a gradually increasing thickness from each end of the cocoon towards the middle, where it is thickest, in some instances by as much as a third. I consider the exceptions to be accidental, and in no way invalidating the theory and discovered fact.

In the diameter of the have, it is noticeable, that towards each end of it the disproportion in diameter of the two fibres, composing it becomes gradually greater, so that often at the beginning or end of the cocoon one fibre or bria is much thicker than the others.

Now, it will be asked, what is the practical outcome for all this? First, a silken thread or fabric is best when equally strong and also

when equally thick or equally thin. As it is always the practice in reeling cocoons to reel, say, four or more cocoon threads together, it is manifestly impossible to reel an even flatness or thread of raw silk if the cocoons are all commenced at the same time, or if cocoons are taken varying much in the sizes of their threads.

This investigation tends to instruct those engaged in reeling the cocoons by clearly showing where the inequalities are, and at the same time to guide them in greater niceties of manipulation, so as to secure as even and perfect a result as possible.

Where the bave differs so much in thickness as one-third, it is impossible to expect an even thread to be constructed by rule of thumb, and I am glad to say that the Chamber of Commerce at Lyons places very high value on these examinations.

Greater attention is paid to this already in Italy, France and Brousses, than, perhaps, elsewhere; although much of the Japanese silk is excellently reeled. I have here a sample of Bengal silk, which has been lent to me by a Leek manufacturer of sewing silks, which he states is so beautifully reeled as to produce silk thread for the sewing-machine, of perfect regularity and strength; but for some time great complaints have been rife as to the unequal reeling, and consequently unequal sizing of China silks. It is impossible to construct delicate fabrics in the loom, where evenness is required, unless the silk is well sized.

The same may be said to a certain extent of the wild silks, but there are somewhat greater irregularities throughout the length of the cocoon in these silks than in the domesticated breeds. In Eria silk, the thickening of the fibres towards the centre of the cocoon is particularly noticeable, in tussur silk, less so; but as only one cocoon has been examined, I do not insist that this exception is constant.

There is no doubt that it is not difficult now to reel tussur silk into very regular even threads. In 1876 I went to Italy, at the instance of the Government of India, to see if it were possible to make a good thread out of tussur cocoons. I was perfectly successful, and the results may be seen at the India section of the South Kensington Museum, and will be found amply described in my "Hand-book of the Wild Silks of India." Since that time a number of collaborators in India and China have been confirming these results. One gentleman in India, who has availed himself of the best European reeling appliances has for some time regularly sent me samples of raw silk of his reeling which have gradually become more and more satisfactory. He now writes saying that there is nothing left to be desired, except to wait for more skill on the part of his young silk-workers; his observation is fully borne out in the opinions of several English silk manufacturers to whom I have submitted his results.

The characteristic glittering appearance of tussur silk when dyed, especially in black, is most probably owing to the fibres being flattish, and the bave becoming separated into its ultimate fibres more easily than in mulberry silk, thus giving play to greater reflection of light.

Owing to the extreme difficulty of obtaining transverse sections of the fibre of silk sufficiently thin, I have not yet been able to complete my investigations on its absolute structure, either in the undyed or dyed state. I am at present engaged on this, and hope before long to be able to describe the appearances, under the highest powers, of sections which must be as thin as, at least 1/4000 inch, in order that they may lie flat on the slide. The importance of this inquiry will be understood, when I state that to such an extent has the falsification of silk arrived by weighting with chemical matter, that in many fabrics the bulk is increased to as much as eight times the original bulk of the fibre. It will also be useful if we can get at a clearer idea as to how tinctorial matter, with and without mordants, permeates or penetrates the silk fibre as well as to the action of certain matters with which silk has a peculiar affinity, as for example, tannic acid, salts of tin, iron, chromium, &c.

SPIDER-SILK.

I come now to a short consideration of spider-silk. As is so well known, spiders are great producers of this fibre, both for their webs and nests.

As the examination of spider-silk is comparatively new to me, I have not had time to make a very minute investigation of it, but it will form the basis of future interesting work.

Professor Threlson Dyer, some time ago, was good enough to ask me to investigate some spider-silk which a correspondent, Mr. Duthie, had sent to him from India, and in describing this, I, think I cannot do better than read first the letter which Professor Dyer received from Mr. Duthie. The letter is dated, "Botanical Gardens, Saharanpur, November 25th, 1884," and is as follows:—

"By to-day's mail I am sending you some queer-looking stuff—spider-silk. It was extremely lovely as I saw it when coming down from Almora the other day. Enormous webs of it stretched between the trees and shrubs overhauling the lake at Bhim Tal in Kumaon. I saw a notice a short time ago, in some paper, regarding the use which might be made of these strange webs. A particular kind, of a golden yellow colour, occurring in New Zealand, was specially recommended, and in fact it had been manipulated with success as a substitute for silk. What I saw at Bhim Tal answers very much to the description of the New Zealand kind, and if a supply is wanted for an experiment on a large scale, it could easily be obtained from this locality, after the rainy season is over. In a small tin-box enclosed in the packet I am now sending are a few of the spiders, not in very good order, but I had to send for them."

Professor Dyer, called in the learned aid of the Rev. O. F. Cambridge, of Bloxworth Rectory, Warham, relative to the natural history part of the subject, and, as the letter is very interesting, I do not think it will be considered out of place here. He says:—

"The spiders are broken, shrivelled, and crushed out of all recognition almost. The genus, however, is clear enough, and

I have no hesitation in pronouncing them to be (an Epeirid) *Nephilengys malabarensis*, Walck. Walckenaer described it as an Epeira, I described it also some years ago from the China Sea and the Congo and other parts of the West African coast (supposing it to be new), as *Nephila reculata*. Subsequently, L. Koch separated it from *Nephila*, under its present (good) generic name *Nephilengys*. It seems to be almost cosmopolitan; it has been described under another name, from Ambonia, by Doleschall, and under another again, by L. Koch as well as twice, under different names, by Walckenaer. I have it from the China seas and India, as well as from Australia, Borneo, and West Africa, and I think (though I cannot at this moment refer to my collection and books) from other regions as well. It appears to be exceedingly abundant in all its localities. The silk (which is new to me) is very strong and tough, and I should imagine that the fabric which might be made from it would be almost imperishable. Whether it could be spun out from silk collected *en masse* from the spider's snares, I should doubt. I fancy the only way to get the silk in condition for spinning and weaving, would be after some such method as Dr. B. G. Wilder proposed, and experimented upon (I believe) successfully, some years ago, in North America. But the great drawback will always remain, that spiders devour each other, and so cannot be fed, or their silk obtained, without great trouble and cost."

After carefully examining this spider-silk, I made the following report:—

"The fibre is evidently of a silken nature, and, like silk, it is loaded with a gummy substance. In a boiling soap solution, this gum, or varnish, dissolves leaving the fibre apparently pure, and of the nature of fibroin, if not identical with it.

"Eight micrometric measurements of the diameter of the fibre in different parts of the mass showed great irregularity in diameter (1/2300, 1/2800, 1/3500, 1/2800, 1/3500, 1/3500, 1/3500, 1/3500) giving an average of 1/3100 inch. It is, therefore, a considerably finer fibre "or brin" than silk, the brin of Italian silk being not finer than 1/2100 inch.

"The average strength of the spider-silk is proportionately greater than that of silk, a single fibre of the spider-silk breaking with an average weight of 2½ drams avoirdupois, whilst that of China silk, so much thicker, breaks at 2 to 3 drams.

"The most curious property of this fibre is its elasticity, which is considerably greater than that of silk; 30 centimetres of it will stretch to an average length of 36·6 centimetres before breaking, whilst China silk will only stretch to 34 or 35 centimetres.

"Like silk, this spider's web-silk is lustrous, and has a round fibre.

"Its coating of gum or varnish is disproportionate to the weight of the silk. On boiling with soap it lost weight at the rate of 7½ ozs. per lb. avoirdupois, that is 1 lb. of the spider silk discharged 7½ ozs of gum. In the silk of the *Bombyx mori* worm the proportion is much less, the gum seldom being over 25 to 30 per cent of the total weight. Before boiling in soap the spider-silk was well combed to remove all the dirt possible, but a little remained.

"The fibre appears to receive tinctorial matter readily. I enclose a small pattern of it dyed, and also one as I received it, and one after boiling in soap.

I believe, if it can be obtained in quantity, it might be packed in bales and sent to England, where it would readily find a market for being carded and spun into spun silk threads for sewing or weaving purposes.

"It is difficult to estimate its marketable value. I dare say it would at any rate realise 1s. to 2s. per lb. It is rather dirty, and this would to some extent detract from its value as compared with silk waste.

"I have tried to discover how many eripositors this spider has, but beyond noticing, under the microscope, that the fibres often run in pairs, but not regularly, I am unable to trace whether there are two, as in the ordinary silk worms, or more. Probably an examination of the spider would show this, or of an undisturbed portion of its secreted silk."

Mr. Cambridge has been kind enough to send me five other species of spider-silks. I have not been able to do more than to examine the diameters of their fibres, which are as follows:—

	Diameters of ultimate fibres.
Egg cocoons of an <i>Epeirida</i> sp.	1/7000 inch.
Egg cocoons of <i>Meta menardi</i> , Latr. Devonshire ...	1/4000 inch.
Nest of <i>Urocyon Durandii</i> , Walk, Palestine ...	1/8000 inch.
Silk of <i>Nephila Plumipes</i> , Koch, United States, America ...	1/2150 inch.
Egg cocoons of <i>Voconia maculata</i> , Kays N. Corrientes, La Plata ...	1/14000 inch.

The small specimens of spider-silks are on the table, and, along with that of the *Nephila plumipes*, is a small portion of ribbon made with its silk for the warp, and with cotton a weft.

There does not seem to be much prospect of any successful reeling of any of the species of spider-silk, but it is quite within the limits of possibility that they may be produced in such quantity as to be useful for being carded and spun, and if so, there will no doubt be a considerable utilisation of them.

Short of a thorough analysis of the spider-silks, which I have not yet had opportunities of making, it seems to possess to all appearance, all the physical properties of mulberry silk. It certainly has a central axis of silky matter probably fibroin, and also an external coating of "gum," or "grea," or varnish, like silk, probably to protect it from the action of the weather.

Dr. Bowman, in his first lecture on "The Structure of the Wool Fibre," at the Bradford Society of Dyers and Colourists, on January 22nd 1884, states that silk fibre consists of three parts—a central silk cylinder forming the principal part of the fibre,

Outside this, is a layer of albumen, and on the surface of this, a thin coat of gelatine. I have not been able to confirm this, and cannot go beyond my observations, which at present limit my conclusions to there being only a central substance of fibroin, coated with what is technically termed in England "gum" and in France "gres," the gum constituting from 25 to 30 per cent of the original weight of the silk, and being entirely removable, by the necessary operation before dyeing, of boiling the silk in a solution of soap.

In the case of the mulberry silks, the fibres seem structureless, having the appearance of a glass rod, and, like glass, have a more or less conchoidal fracture when broken. Wild silks differ from this in structure very much. In almost all of them, each fibre seems to consist of minute fibrils, and under the microscope appear numbers of thin, longitudinal striations throughout the length of the fibre. In the case of tussur silk, I have been able to separate these fibrils, as you will presently notice on the screen.

I ought here to mention two properties of silk which have to do somewhat with structure and practical manipulations.

First, silk is more or less affected by water, and always holds in what Dr. Bowman calls a state of water of hydration, containing more in damp weather and less in dry weather. At the Lyons conditioning-house, silks sent to be conditioned are made absolutely dry at a high temperature in suitably constructed vessels. They are then weighed, and 11 per cent is added to the dried weight for water of hydration or natural moisture. During the last twenty years I have made an enormous number of trials of this hygrometric property of silk, and I have found that when silk, having been divested of its natural gum and dried at a temperature not exceeding 150° Fahr., is exposed to the air, it gains in weight from 5 to 10 drams per boiled-off silk-lb., or from 2 to 4 per cent. This shows also that a much higher temperature is required to drive off all the water of hydration.

Second, the electric properties of silk are remarkable. Silk is a most perfect non-conductor of electricity when dry, and it is amusing to see how loose dry silk fibres start up in *cheveux de frise* fashion when excited by friction. This property seriously interferes with the manipulation of silk in various stages of its manufacture when it becomes too dry. In some manipulations it has to be kept moist by artificially applied means, such as glycerine, &c. It will be seen from this how much more suitable our colder and moister English climate is for silk manufacture than hotter and drier ones.

With regard to the chemical composition of silk, there is a little perplexity. Probably the most satisfactory examination yet made, is the following, by Mr. Schorlemmer:—

"When raw silk is heated in water under pressure, it yields two compounds.

"Fibroin, $C_{15}H_{23}N_5O_8$, constitutes about 66 per cent of raw silk; it is a silky, glistening substance, which is insoluble in water, but dissolves in strong acids, alkalies, and a solution of cuprammonium sulphate. When boiled with dilute sulphuric acid, it yields glycocoll, leucine and tyrosine.

"Sericin or silk-gelatin, $C_{15}H_{23}N_5O_8$, is a substance resembling gelatin. Its hot aqueous solution is precipitated by alcohol, and after drying, the precipitate forms a colourless powder, which in cold water swells up to a gelatinous mass. On boiling it with dilute sulphuric acid, it yields a small quantity of leucine, and larger quantities of tyrosine and serine, or amidoglyceroic acid."

Dr. Bowman, in his most excellent lectures on wool fibre, gives some interesting facts in his third paper on wool fibre, from which I will quote, and it will be interesting also to give the composition of cotton and wool fibres for comparison.

Perfectly pure cotton is identical with pure cellulose, which is represented by the formula given in the following table, where the formula for silk is contrasted with those for wool and cotton:—

Cotton	$C_6H_{10}O_5$
Silk	$C_{24}H_{28}N_5O_8$
Wool	$C_4H_{15}SO_{15}$

The important additional element of nitrogen in silk and wool will be observed, as well as wool standing alone in containing sulphur.

I hardly think that this is the right way of stating the formulae for silk. I am inclined to doubt their accuracy, for it is not quite clear that silk is purely an organic substance. If pure silk is fibroin, its formula would be as stated by Mr. Schorlemmer, $C_{15}H_{23}N_5O_8$; but if the composition to be described is that of the fibroin, sericin, albumen and gelatin contained in silk as it exudes from the silk-worm, it can hardly be formulated as a distinct chemical compound.

I may here state, in passing, that Dr. Wanklyn's admirable ammonia process for estimating the amount of organic matter in water, is applicable for determining the exact amount of silk when in combination with weighting matter. I am at present at work on this, and as soon as the results are worked out, I intend that they shall form the substance of another paper in connection with details concerning the *modus operandi* of silk weighting, now so very largely practised on the Continent of Europe, and to a certain but more limited extent, I am sorry to say, in England, where in recent degenerate days foreign competition in price has rendered it more or less imperative. It will be of the highest importance to describe a method by which chemists can at once, with certainty, determine the exact amount of sophistication in any so-called silk fabric.

Is not the time arrived when the British consumer should know by the compulsory declaration of the amount of weight or adulteration what he is really buying? I think so.

I also give from Dr. Bowman's lecture the composition of wool, and also of horny tissue, which it resembles very closely:—

Average Composition of Horny Tissue, according to Mulder.

	Per cent.
Carbon	50.64
Hydrogen	8.91
Nitrogen	18.83
Oxygen	22.77
Sulphur	8.85
	100.00

Composition of Wool.

	Schöerer.	Mulder.
Carbon	50.85	50.6
Hydrogen	7.03	8.8
Nitrogen	17.71	18.8
Oxygen	24.61	20.5
Sulphur	0.00	5.4
	100.00	100.0

Dr. Bowman found that, after drying, a number of samples of wool at about 100° F., and then exposing them to the air in an ordinary warehouse unheated in any way, but with a temperature of about 50° F. to 60° F., there was an average gain of 8.28 per cent of moisture, which he terms the water of hydration. He also says:—

"That on the Continent there are official and public testing establishments in many of the large manufacturing centres, both in France and Germany, where reports can be obtained in regard to the condition both of wool tops and yarn, and that it has been found, by a number of experiments conducted in these places, that if wool is subjected to the highest temperature which it can sustain without scorching, it will regain from 18 to 18½ per cent of moisture, and that we may therefore regard this as its normal condition under the usual atmospheric conditions.

"The above analyses are analyses of the residual or pure wool after the fat, sweaty matter and yolk or suint have been removed by treatment with hydrochloric acid, anhydrous ether, cold water, and alcohol in succession, and then again exhausted with alcohol and ether. The quantity of these foreign substances amounts to from 20 to 50 per cent in air-dried wool."

The following table will show the position in the animal kingdom of the silk-worms and spiders which have produced the silk described in this paper:—

DIVISION III.—ARTICULATA.

SUB-DIVISION II.—Anthropoda (or true articulata).

Class, Insecta.	Class, Arachnida.
Sub-Class, Metabola.	Order.
Order, Lepidoptera.	Family, Epeiridae.
Sub Order, Heterocera.	Group, orbicularis, or Geometric, Web-weavers.
Group, Bombycina.	<i>Nephilengys malabarensis</i> .
	<i>Meta monardi</i> , Latr.
Family, Bombycidae.	<i>Nephila plumipes</i> , Koch.
Genus, Bombyx.	<i>Epeirida</i> sp., Adels.
Species, <i>Bombyx mori</i> .	Family, Uroctoides.
	Group, Tubularis, or Tubular. Nest-spinners.
	<i>Uroctea Durandi</i> , Walck.
	Family, Thomisidae.
	Group, Laterigrada, or laterally extended-leg spiders.
	<i>Vocota maculata</i> , Kays.
Genus, Attacus.	Genus, Anthema.
Species, <i>A. Cynthia</i> .	Species, <i>A. Mylitta</i> .
<i>A. ricini</i> .	<i>A. yamamotoi</i> .
	<i>A. Assama</i> .
	<i>A. pernyi</i> .

COMMERCIAL ASPECTS OF THE SILK INDUSTRY.

The necessity for the minutest inquiry into every detail concerning the economy and excellence of manufacturing silk, cannot be over-estimated. The fact of the Lyons Chamber of Commerce, at this late period of the history of so successful a silk industry as theirs, commencing to build a laboratory for more minute investigation, proves it.

Our attention is almost compulsorily arrested by the fact of the decadence of this industry in our own country, a decadence threatened by extinction, gradual but sure.

A few useful figures from the Board of Trade returns of the value of the imports into the United Kingdom, and of the exports of British and Irish produce from 1854 to 1884, ordered by the House of Commons to be printed in 1882, most seriously shows this. I will only give the totals of various kinds of silk goods manufactured by countries in Europe during two decades, and purchased by England.

* Dr. Bowman's Lecture on Wool Fibre at the Bradford Society of Dyers and Colourists, April, 1885.

IMPORTS OF SILK MANUFACTURES FROM THE CONTINENT OF EUROPE, DECADE 1854 TO 1863.

	£
Broad stuff, silk and satin ...	13,679,321
Broad stuff, velvet ...	1,882,870
Ribbons of silk and satin and other kinds ...	14,176,544
Flush for making hats ...	1,023,748
Other kinds of unenumerated manufactures, all silk, and silk mixed with other materials ...	3,470,852
Total ...	33,732,335

DECADE 1874 TO 1883

	£
Broad stuff, silk and satin ...	63,868,365
Broad stuff, velvet ...	8,456,076
Ribbons of silk, satin, and other kinds ...	18,919,378
Flush for making hats ...	237,193
Other kinds of unenumerated manufactures of all silk, and silk mixed with other materials ...	26,829,580
Total ...	118,310,572

In 1855, our total imports of manufactured silk from countries in Europe amounted to a value of £1,826,525.

In 1880, the total imports of manufactured silk from countries in Europe had grown gradually year by year in value to £13,085,083.

Thus in 25 years we had come to buy from countries in Europe of articles we ought to have manufactured for ourselves no less than £11,258,558, an almost incredible sum.

Did we lose this industry, or was it only a surplus to our then established silk industry? The distressed state to day of Coventry, Congleton, Macclesfield, and Spitalfields, and the Manchester silk districts, answers this question too painfully. The trade is gone practically, and gone from us to more skilled and persevering centres abroad, and gone, too, from our own country, which possesses the most suitable climate in the world for the silk manufacturing operations of winding, throwing, dyeing, warping, and weaving.

The valuable reports of the Royal Commission on Technical Instruction, of which Commission my friend, Mr. Woodall, M. P., who has done me the honour to preside this evening, is a most hard-working member, not only fully shows how large an industry there is abroad, but insists that it is only by equal technical skill and increased art-knowledge that our old silk trade can be re-won.

The breeding of silkworms has for a long time been a most important industry in Italy and the south of France. The total production of cocoons from these worms in Italy amounted, in 1881, to 39,300 tons and in 1880 to 40,930 tons in France in 1881 the production of cocoons amounted to 20,362,179=9,090 tons, and were principally raised in the Departments Gard, Ardèche, Drome, Vaucluse, Var, and by the mouths of the Rhone. French statistics show that from this large quantity of French cocoons was produced, in 1881:—

	Raw silk.	
	lbs.	tons.
France ...	1,650,000	or 737
Italy ...	6,523,000	2,912
Corsica and Algeria ...	6,182	3
Austrian Hungary ...	324,632	145
Spain and Portugal ...	184,800	82
Total product in West Europe ...	8,688,614	3,879
From the Levant:—		
Turkey:—		
Anatolia ...	158,400	71
Salonica, Volo, Adrianople ...	264,000	118
Syria ...	365,200	163
Greece ...	28,600	13
Persea and Georgia ...	550,000	246
	1,366,200	611

It will be seen from these figures what a very important matter it is that the greatest attention should be paid to the earlier operations in the manufacture of silk threads, and one cannot be surprised at the Lyons Chamber of Commerce starting anew to ascertain all the facts relative to the proper sizing, i. e., producing even threads of silk in a more minute and exact manner than heretofore. For if the earlier stages and operations have not for their aim and effect the production of an even thread, no after-manipulation of winding, warping, dyeing, weaving, or finishing can effectually avail in turning out fabrics of the finest qualities, in all or any of the various purposes for which silk is used. Hitherto the sizing has been by rule of thumb, and dependent on skilled eyesight and fingers, in first sorting cocoons and afterwards reeling 4, 6, 8, or more together, according to the required thickness of thread or what at this stage is termed raw silk, that is the state in which it comes into the market before it is manufactured into organzine, tramingles, &c. An examination of the thickness of the ultimate fibre must then take first place, and this method has now commenced, and will be carried on in the new Lyons Laboratory not only of all species and varieties, or, as the French call them, races, of cocoons, but of the thickness of these fibres throughout the entire length of the cocoons, which I have discovered to be very variable. Next come the important examinations of strength and tension, or elasticity,

which the foregoing tables illustrate in both the silks of domesticated and of wild worms.

The necessity for examinations such as these is more apparent in the manufacture of those silks which, some years ago, I ventured to designate by the name wild. For some of the wild silks of India for example, there is a great future, a prediction warranted by the successful employment of the wild silks, Tassar—or as it is termed in its vernacular, Tassar—during the last seven years. It would not be right to omit here the mention of the name of Sir George Birdwood, C. S. I., M. D., in connection with Tassar silk.

In my South Kensington Museum "Hand-book of the Wild Silks of India," I quoted a paper which he wrote in India, as long since as 1839, in which he advocates the desirability of an attempt being made in England to utilise Tassar silk, a suggestion which he has lived to see now abundantly realised.

The extent to which the consumption of Tassar silk in Europe has reached is very large. France imported, from one port alone, last year, 8,000 bales of raw Tassar silk. Several English manufactures have thrown during last year large quantities, as high, in one instance, as 1,000 bales. The whole of these recently increased imports may be said to be badly reeled from the cocoon, much of it very badly reeled indeed, causing the European manufacturers to cry out loudly for improved reeling in the Eastern centre of production. Already has the improvement begun, and to such an extent has it been proved practicable by one of my many correspondents and collaborators in the East, that raw Tassar is produced from a single bave only—that is, so delicate in the improved reeling, that the beautiful raw Tassar you see here is simply the double fibre from a single cocoon reeled into a single thread successfully, proving conclusively enough that in this, as in other species of silk, if the quality of the raw silk put in the market is defective in any way it is not the fault of the silkworm, which always does its work with the precision that the honey bee builds her cell, but rather the hitherto inadequacy of perception of man to ascertain and adjust the natural variations and differences of the fibre of so wondrous a beauty, and so incomprehensible a product.

If this contribution to a more exact understanding of silk fibre shall serve in however small a degree to stimulate any persons in the direction towards the recovery of our almost lost industry, my object and aim will be fully served.

My acknowledgments are due to my assistants, Mr. T. Rigby, and to my son Bernard, for their care and help in the examination of silk fibre for this paper.

I am indebted to Messrs. Bullock and Sons, silk merchants of London and Macclesfield, for the various specimens of raw silk lent for exhibition.

POISON MILK AND ITS CAUSES.

The following article on this subject appears in the *Congregationalist* of Boston Mass. It applies directly to the United States, as the reference to "green (Indian) corn" shows; but what the writer describes is as much an evil in this country as across the Atlantic:—

The Romans exposed their superfluous children in the Lupercal, and thus made summary work with them. We take ours through longer and more refined torture, but succeed in destroying many of them before the age of five. It may be questioned which indicates the greater barbarism.

One of the most potent instruments in this destruction has for some reason received little attention—the feeding of green, succulent food to cows. Every dairyman is familiar with the laxative effects of green corn, &c., upon his cows. Now no principle is better established than that the animal excretions go very largely into the milk; how quick, for instance, a feed of turnips will produce its effects. Hence it might be expected that, if the cow be purged, the babe fed upon her milk will be; and that this is actually the case, and in a dangerous degree, and any one can satisfy himself by a very few experiments. It will be found, I think, that a single feed of green corn, the "trimmings" of a dinner of green vegetables, or anything of a like nature, will at once produce harmful effects on the child.

I tried this carefully a few years ago, feeding very cautiously and keeping the thing from the knowledge of the mother; but every time the green food was fed, be it a single foddering of green corn, a few pea pods, or the trimmings from a few summer squashes the ever watchful mother would attack me with, "What has the cow been eating lately?" One night the cow got into the corn and ate quite heartily, and the children were made sick for a week, the youngest seriously so. It is well known that the change of the cows from dry pasture to succulent clover or "fall feed" will produce for a few days the same effects, but the cows soon get used to it and resume their wonted condition. Thinking the same result would occur with the children, I kept up the cautious experiment for some time, till it became plain that if I did not give it up the children would, when a change was made with entirely satisfactory results.

The season is at hand. Corn fodder and similar foods are to be given to all the cows in the greatest profusion, to keep up the utmost possible flow of milk, regardless of quality or effects. And the consequent diarrhoeas and dysenteries will begin to carry off the bottle-fed infants by thousands. There is no reason why a babe should not be reared perfectly well on artificial foods, only great care must be taken, especially with the cow. A whole-souled milkman of my acquaintance, whenever he "has a baby on his hands," as he terms it, takes a good cow from the green fodder and feeds her upon dry food alone, and then keeps that milk carefully for the babe. So much he learned to do by his experience and he deserves a medal; but how many such milkmen are there?

A little inquiry will show any one that this is a matter of serious import, deserving investigation, if not a crusade. Those having a family cow of their own (as every family should, when possible),

* The velvets for 1883 are included with broad stuffs of silk and satin.

can usually avoid trouble by wilting the green food well for two or three days; but, of course, the milkmen will not do this, as it costs labour and seriously diminishes the flow of milk. In the larger places there would seem to be no alternative but to encourage certain milkmen to make a speciality of furnishing milk for babies, and then guard the purity of such milk by stringent laws and rigid inspection.

In this connection the silo must not be forgotten. Every one knows the effect upon the child of alcohol drunk by the mother. Now, with all its desirable qualities, the silo has this, also, that it is an alcohol or acetic acid producer of the most villainous sort. The effects, then, of silo-fed milk upon young children cannot fail to be dangerous to the last degree, and no mother should use it who does not wish to run serious risks. It will not be long before the physicians will begin to sound the alarm on this point, as indeed some of the more vigilant have already done. In these days of societies for the prevention of cruelty to animals and cruelty to children, of praying crusades and C. T. U's, why is there not some one to stir a woman's crusade in behalf of our half-million of little ones every year in these wicked ways needlessly slaughtered?

THE SOILING OF DAIRY STOCK.

In a paper read before a recent meeting of the Liverpool (England) Veterinary Association on the above subject, the writer sums up the advantages of the soiling system in the following condensed form:

1. Increased production of milk.
2. Superior quality of milk.
3. Better condition of animals as compared with those grazed.
4. Economy in consumption of food.
5. Great saving of land.
6. Waste land now occupied by fences, materially dispensed with.
7. Increase in the quantity and improvement in the quality of manure.
8. Value of land produce increased.
9. Protection afforded stock against various forms of disease, infectious and non infectious, and parasitic invasion.

He then enlarges upon each of the above heads to prove the correctness of the positions, but space will not permit our publishing his article entire. That upon the first head, briefly summarized, is to the effect that in pasturage the cow expends a considerable amount of physical energy in travelling over the pasture in search of food, when if the food was brought to her, she would only take such exercise as the calls of nature demand, and would spend the rest of the time in quiet rumination, and the energies otherwise taxed in gathering her food would be expended in the secretion of milk. He estimates that the production of a herd of cows under soiling is one-third greater than if on pasture. He claims that the same conditions which increase the quantity of milk, also improve its quality. Soiling is being more and more adopted by American dairymen, especially where lands have become valuable. One of the strongest advocates of the system in the west is Hon'ble Hiram Smith, of Sheboygan Falls, Wis., who claims that the dairymen by this system can double the cow keeping capacity of the farm. In the east where much of the area of the farms is rough broken land, suited only for pasturage and where the tillable area is needed for meadow and grain, pasturage must continue the rule. But on the prairie farms of the west there are no natural obstacles to its adoption by any farmer who may see fit for his advantage to do so, either wholly or in part. We have five crops which will supply all the material needed, and furnish ensilage for a continuation of the feeding of succulent fodder during the winter; these are winter rye, clover, oats, millet and fodder corn, which will be in condition for feeding in the order named, carrying the dairyman through the entire summer without any break in the supply of green food required for his stock. They all make good ensilage, and any supplies not required for summer feeding can be so utilized or cured for dry fodder. Where soiling is intended next season, the rye should be sown this month so as to get a good start before winter. The subject presents to the western dairyman this problem to work out: Will the increased product from the increased amount of dairy stock which the farm will carry under the system of soiling, including the increased quantity and improved quality of manure saved, pay the extra labour required, and leave a profit above what would be realized from pasturage? Each dairyman must answer this question for himself from the knowledge he has of his own conditions and environments. Our own belief is that wherever farms have reached a value of \$40 per acre the answer will be in the affirmative. One thing not involving immediate profits should not be lost sight of: The increased amount of stock that can be carried under the soiling system will steadily improve the fertility of the farm so that year by year heavier crops can be grown upon it, thereby increasing its actual value either for use or sale.—*Farmers' Review*

HOLLOWAY'S OINTMENT AND PILLS are the best, the cheapest, and the most popular remedies. At all seasons, under all circumstances, they may be used with safety and with the certainty of doing good. Eruptions, rashes and all descriptions of skin diseases, sores, ulcerations and burns, are presently benefited and ultimately cured by these healing, soothing and purifying medicaments. The Ointment rubbed upon the abdomen, checks all tendency to irritation of the bowels, and averts dysentery and other disorders of the intestines. Pimples, blotches, inflammations of the skin, muscular pains, neuralgic affections, and enlarged glands can be effectually overcome by using Holloway's remedies according to the "instruction" accompanying each packet.

FACTS AND FIGURES.

[From *Kuhn's*.]

ENGLAND consumes in a year 54,452,255,000 feet of gas. It is said that thirty thousand hands are employed in the manufacture of roller skates.

Four thousand suits are said to have been begun in New York on charges of selling adulterated milk.

The maize harvest of the ten principal States in the west of America will this year be quite 1,436,236,000 bushels or 185,840,000 bushels more than last year.

In 1860 the United States had 141 cities and towns of over 8,000 inhabitants, and now there are 236 of such cities and towns. Then the total population of her cities was 5,000,000; now it is about 12,000,000.

The districts producing coal and lignite in Austria may be ranged in the following order: Bohemia, 73 per cent; Styria, 19 per cent; Upper Austria, 3 per cent; Moravia, 1 per cent; Karain, 1 per cent; Corinthia, 0.9 per cent and Istria, 0.6 per cent.

The woollen industry of the United States employed 60,000 persons in 1880, and now 160,000, while the home mills, which produced goods of the value of \$30,000,000 in 1880, now turn out an annual product worth \$270,000,000.

During the past season 62,000,000 lb. of tea were exported from Hankow and Shanghai, 34,000,000 lb. from Foochow, and 13,000,000 lb. from Canton, or 109,000,000 lb. altogether, against 111,000,000 lb. in 1884.

There were 6,004 failures for 74,722,353 dollars in the United States and 690 for 5,166,185 dollars in Canada during the first half of this year, against 5,510 and 752 failures respectively, and 124,301,282 dollars and 10,742,600 dollars respectively during the same period of 1884.

Fine ribbed stockings were made by machinery in England as early as 1755.

French Railways annually kill one passenger in every 2,000,000 carried; English railways, one in every 21,500,000.

A manufacturer of Breslau has built a chimney 6 metres high entirely of layers of compressed paper, jointed with cement.

The annual oyster trade of New York amounts in round numbers to 5,000,000 bushels.

Fifty thousand letters are said to be sent daily to the United States President, who requires ten thousand clerks.

An enormous supply of copper from the Lake regions of the United States is said to be assured for the next 75 years.

There are somewhat over 220 furnaces in blast in the United States, the greater part of the furnaces being at present out of blast.

There is a talk in Cleveland of a process of making iron more directly from the ore than has hitherto been done, and thus considerably cheapening the product.

A steamer which arrived at San Francisco recently brought nearly one hundred thousand seal skins, valued at over a million dollars.

There is a well of natural gas at Murrsville, Pa., that has been flowing for ten years, and it is said there is no diminution of pressure, though as good a well has been struck within thirty feet of it.

A mass of granite estimated to weigh at least 500,000 tons was displaced recently on the line of the Iron Mountain Railroad, in Missouri, by a single blast in which 5 tons of powder were used.

The throne of the Empress of Russia is completely covered with plates of gold, and contains 1,500 rubles and 8,000 barquoises, besides many other rare and costly gems. The throne of the Czar, known as the diamond throne, is truly a marvel.

TUBERCULOSIS IN CATTLE.

SIR,—I have been accused for quibbling, and if I have, I am sure nothing was ever further from my intentions. The subject is too serious a one for either that or writing for mere argument's sake. It will be observed that Professor Walley wavers, and cannot withstand the artillery of common-sense logic; he resigns one of his strongholds, and now waives the slaying of cattle on strong presumptive evidence. This point cannot be too strongly emphasised, for if a professional man was to order the slaughter of an animal worth, say, £500 or £600, and on a *post-mortem* exploration find no tubercle, where would the compensation come from? Besides, would he not find himself in a very awkward predicament as to the curability of consumption? I consider no disease that we generally meet with incurable at a certain stage; it is only us that have not arrived at the knowledge how to apply the means properly as to the malady under consideration. I shall not be so egotistical as to say what share I consider I may have had in the cure of animals entrusted to my treatment, but shall content myself by showing that the disease is considered curable. Allow me, then, to quote a passage from your well-known townsman, the late eminent Dr. Warburton Begbie. He says—"Consumption, as is very well known, was long considered to be incurable. It may, however, now be regarded as a curable disease, that is to say, persons affected with the general symptoms and presenting the physical signs (as determined by auscultation, percussion, &c.) of tubercular deposition on the lungs in all its stages, do again acquire a fair share of health and strength—in some rarer instances a complete restoration of both occurs; while the physical signs, being for the time stationary, afterwards undergo such modifications as are alone reconcilable with favourable changes occurring in the lungs." This opinion may be objected to by some, but it is grounded on carefully-observed facts, recorded, moreover, by those who are the most skilled and eminent in the profession of medicine. A further and most corroborative testimony is found in the morbid anatomy of tubercular disease of the lungs. Appearances in these organs are

frequently met with which are now almost universally accepted as the evidence of a retrograde process of a healing or curative action. This subject deserves an open and straight-forward discussion, which I do not think Professor Walley wishes it to have, as further on he attempts to point out that the word meningitis can only be applied to the brain lining, and not to the linings of the chest and bowels; and I do not know that these experiments that he talks of were ever tried after an animal's recovery. And it must be observed that this disease is not the same as pleuro-pneumonia, rinderpest, or foot-and-mouth, that are under the operation of the Cattle Contagious Diseases Act, as these are foreigners, and can be stamped out by slaughtering and disinfecting. But tuberculosis really cannot be by these means. It is home-bred disease; and although every affected animal were slaughtered, &c.,—which seems an impossibility—before many months were past, in the present state of matters, there would likely be a pretty good beginning. I cannot help stating again that it is my conviction that this malady is not infectious in the ordinary sense of the term. I was intimately acquainted with the late Mr. Dewar, and once accompanied him in a three hours' post mortem of a tuberculosis cow, but at that time there was no word of infection or contagion. I have seen a whole herd have to be cleared out, but not at all from infection, but in-breeding heredity; and I have seen 15 or 16 affected, all blood relations, and, without using precautions of any kind, none of the rest became affected. The only cases of suspicion of contagion I can call to mind were those standing in continuous contact in the same stall, and it struck me forcibly that the nasty breath and sour smell of the sick animal played no mean part in the primary cause of the affection, by putting the stomach and constitution out of sorts. Moreover, allowing it to be contagious, and although cattle were rid of it to-morrow, where would the safety be so long as mice, rabbits, pigs, &c., are subject—especially subject—to contract it; and men and women who might unfortunately be victims going about squirting the spatum in the fields, the byres, on their food, &c., and while there is the number of latent cases that we know must exist from seeing so many scrofulous calves? And Dr. Bagbie, in his practical and useful little volume, *Medical Information and Advice*, says that the medical profession of this country do not consider tuberculosis infectious. I think I gave my opinion distinct enough about the use of milk in my last letter, and beef also, produced from animals being, or having been, affected actually by tuberculosis; and does not the fact that there must be many cows suffering from latent consumption in dairies supplying human beings with milk, and also that it is quite within the reach of possibility that many more, from a change of food, localisation, climate, and other sanitary surroundings, may be the victims of spontaneous or natural arrestment of this dreadful malady, teach Professor Walley that it is our duty to examine the udders of all cows coming under our charge? And yet he has the assurance to say, teach us. What us? He and his staff of professors? I fear that would be a needless job, since the principal appears to have already made up his mind.—I am, &c.,

—North British Agriculturist.

J. H.

THE ENSILAGE COMMISSION.

THE Private Ensilage Commission has presented the following preliminary report to the Agricultural Department of the Privy Council:—

The Commissioners have, up to the present time, held 11 sittings and examined 38 witnesses, comprising among their number owners and occupiers of landed estates and their agents, tenant farmers, designers and inventors of different forms of silos, or of different systems of applying the necessary weights to stacked or ensiled green fodder, chemists, and authors of pamphlets on the general subject. They have also had the advantage of hearing the views of Sir John Bennett Lawes, whose eminent knowledge of all matters relating to the chemistry of agriculture, combined with the fact that his published opinions on the process of ensilage have been regarded as unfavourable to the system, has rendered his evidence of great value and interest.

The Commissioners have by no means desired to exclude unfavourable evidence; on the contrary, they have endeavoured to induce some of those who were believed to be opposed to the system to give them the benefit of their opinions, but they have so far heard no expression of any decidedly unfavourable views. The evidence tendered has been entirely voluntary, all witnesses attending at their own expense. The evidence of all those who have practically tested the various methods of converting green fodder crops into preserved food for animals without putting them through any process of drying, such as is necessary in the making of hay, has, without exception, established their claims to a considerable amount of success; and, although in some cases, the results have been evidently more satisfactory than in others, the advantages which the different operators, one and all, have claimed for their systems seem to show that a nourishing and useful food for animals can be preserved, independently of any drying process, within wide lines of divergence in the details of the methods adopted.

It has been conclusively shown that, by different degrees of weighting and of expulsion and exclusion of atmospheric air from the material stacked or ensiled, different degrees of heat and of consequent chemical change are produced.

The degree to which such chemical changes increase or diminish the feeding value of the silage itself, or its relative value in comparison to the green crop, is, in the present state of knowledge, in great measure a matter of opinion, and careful feeding experiments conducted with a view to test the exact effect of these changes will be highly important to a solution of this question.

Silage which has been covered in immediately after cutting, and not again uncovered, has been shown to retain its colour and freshness, although developing small quantities of certain acids indicative of a process of fermentation without any considerable accession of heat. Other silage which has been put in at intervals and from which the air has not been immediately or entirely excluded, has undoubtedly developed considerable heat, and in this case the colouring matter of the leaves has been less well preserved. Yet in both cases a useful feeding material has been rendered available which, in unfavourable weather, would have been practically lost if any attempt had been made to convert it into hay.

Bearing in mind the importance of economy, the Commissioners have inquired into the efficiency of various systems of stacking unchaffed green fodder crops without drying, by which it has been contended that, with a proper system of pressure, the necessity for a silo can be done away with.

The Commissioners are not at present prepared to express any opinion upon the economy of any such system, or to compare its advantages with those which are claimed by the advocates of chaffed and close stored silage; but it seems to be established that a temperature sufficiently high to involve danger of fire can be controlled by a proper and efficient system of applying weight to the stack of green fodder.

The different systems of applying weight have greatly occupied the attention of the Commissioners, but as the quality of the silage does not appear to be materially affected by this question, it becomes simply one of economy, and may safely, for the present, be left to each operator to decide for himself, according to the special circumstances affecting the particular locality in which his farm is situated.

Some of the best samples of chaffed silage have been produced with pressure not exceeding 70lb per superficial foot, but the degree to which weighting is necessary or desirable, remains to be decided upon the greatest amount of evidence that may become available to us. Good results are claimed to have been obtained by means of weights varying from 7lb. to 300lb. per superficial foot on the top of the silage.

The experience of dairy farmers does not appear to justify the assertion which has been more or less circulated that dairy produce is, in any way, injuriously affected by silage as food; on the contrary, much valuable evidence has been received to show that the feeding of cows with well made silage distinctly improves the yield of milk and cream, and the quality of butter.

Where complaints have arisen of milk becoming tainted, the cause has been, in our opinion, traceable to its having been in proximity with strong smelling silage, or with persons who have handled it, rather than to the use of such material as food.

The Commissioners have already heard sufficient evidence to justify them in encouraging the development of the system of storing undried green fodder crops as a valuable auxiliary to farm practice. In addition to other advantages, the losses, occurring through weather unfavourable for haymaking, may be avoided, and some crops not hitherto grown in this country on account of the impossibility of ripening their seed (such as certain varieties of maize), may probably be successfully cultivated in certain districts, to the increase of our present means of feeding various kinds of live-stock on arable or partly arable farms.

August 5.

It will be necessary to explain in a few words the nature of the Commission which has thus reported, and the circumstances under which it was appointed. The genesis of ensilage would have to be sought in remote ages and countries, but its modern practice, in Europe and America, has but a very recent history; a decade would include all issues of importance. In this country three years ago, the practice of ensilage was non-existent, but it was commenced on a small experimental scale. The known number of silos in 1882 did not exceed half-a-dozen. In October, however, of that year, a description of the practice as followed on a large scale in France, Holland, and America was given, in these columns, and drew the general attention of agriculturists to the subject. Samples of ensilage and plans of a silo were forwarded to the then so-called Commercial Department, Board of Trade, by Mr. Kains-Jackson, and later the Prime Minister was questioned in the House of Commons on the subject, and he directed inquiry to be made thereon at the English Embassy in Paris.

Silos in 1883 began to multiply, and at the Royal Agricultural Show at Shrewsbury the first silo was publicly exhibited, being opened by the president, the late Sir Brandreth Gibbs. In 1884, the new Agricultural Department at the Privy Council Office, in the annual statistics collected, gave the number of silos as 610, and the process as a farm practice has so generally extended that a competition for prizes invited at the Smithfield Club, and where only some 30 entries were expected, quite ten times the number of samples were received from all parts of the kingdom, revealing an interest that was really national, and forming the first great display of ensilage in the world, although England had been about five years behind France and America in commencing the system. By this time also the Royal Agricultural Society had collected and published much information on the subject so generally favourable to the practice, that Mr. Henry Woods, who had first succeeded with the system on Lord Walsingham's estate in

Norfolk, seemed justified in styling the process a revolution in farming; while the words of this year's President of the British Association, Sir Lyon Playfair, spoken two years previously, "When ensilage experiments have been carefully conducted I have never seen a failure," were endorsed by the general excellence of the samples exhibited at Smithfield. The practice of ensilage had, therefore, become a fit subject for full inquiry to be made into its value at the instigation of Mr. Kaine-Jackson, and an independent and private Commission was instituted, holding its first session at 44, Parliament street, at the office of the Privy Council, by the courtesy of the Agricultural Department. The minutes of evidence received by these private Ensilage Commissioners during March, April, and June have, together with the Preliminary Report printed above, now been published as a Blue-book in a return to addresses made in the House of Commons by Sir Joseph Pease and Mr. Mitchell Henry, and in the House of Lords by Lord Fortescue and Lord Wemyss.

As regards the constitution of this Commission, Lord Moreton asked, in the House of Commons, how it was appointed, when Mr. Trevelyan, in reply, said it was a private, self-elected Committee, which had applied for permission to meet in the rooms of the Agricultural Department, and that the Lord President had allowed them to do so. This answer was a little inaccurate as regards "self-election" (seldom satisfactory), since Commissioners had been selected and solicited to act by the instigator of the Commission, on account of their special knowledge of the ensilage process, their general acquaintance with husbandry, and as representative of Scotland and Ireland, as well as of England, as the list of names attests.

On behalf of the Commission, Mr. Kaine-Jackson issued from the Agricultural Department of the Privy Council a circular early in the year, inviting "the exhibitors at the late ensilage competition and other proprietors of silos in Great Britain and Ireland to give their assistance, by direct evidence or otherwise, to further an inquiry into an agricultural system alike important to land-owners and tenant-farmers." The fact of the whole work being honorary and unpaid appears to have been rather an inducement than an obstacle to the inquiry. The testimony of the witnesses forms the Minutes of Evidence just published in a Blue-book of 212 pages, in which are nearly 5,000 questions and their respective answers. Lord Walsingham, the chairman, who attended every sitting and put the leading questions, is therefore by far the chief contributor to the volume, although all the Commissioners attended frequently and took an active part in examining the witnesses. The preliminary report now issued is signed by all the Commissioners, and while it is reserved in its language, it is decisive in its main conclusion. Much documentary evidence has been already received, and more doubtless will be forthcoming, as to the present season's practice, since we note in one of the questions, the chairman invites Sir John Lawes to attend at the end of the year, and probably the Commissioners' general report is deferred to accompany the completed documentary evidence.

The four cardinal virtues claimed for the process of ensilage appear to be (1) its safety in all seasons, its efficiency, and notably the avoidance of loss in the preservation of green crops; (2) the value of its products as food for animals, and its beneficial effects on the health of all stock to which it is given with discretion; (3) its utilization of substances almost valueless or otherwise waste; and (4) the elasticity the system affords for cropping the land, and in providing a succulent food available all the year round, by which an increased number of stock per acre can be maintained.

Certainly, the evidence may be said fairly to establish these points, and the Ensilage Alphabet of Inquiry circulated by the Commissioners takes them up in detail. It may be here mentioned that the reported evidence is from the notes of a short-hand reporter experienced in "commission" work, while as representatives of the Press were admitted to every sitting, the general tenour of the evidence is substantially already known. Under the letters of the alphabet with numerals for sub-subjects the inquiry thus classifies the information sought.

A.—(1) That the preservation of green crops by the ensilage process is a valuable auxiliary to farm practice, (2) affording safety to the whole crop produced, and (3) given elasticity and economy to crop rotation is answered by most witnesses affirmatively, several of them asserting that they could keep 20 to 50 per cent more stock than under former systems.

B and C referred to the construction of silos and various details of working them. Most of the silos appear to be constructed above or partly below the ground level, a few, and some of the best, being altogether below ground. Witnesses were unanimous in advocating efficient treading of the forage, whether chaffed or unchaffed, whatever the system of pressure or weight per superficial foot. In an analysis of the prices given at the last Smithfield Cattle Show at which there were no fewer than 340 competing samples, it was noted that silage compressed by means of dead weight took 27 prices and commendation out of 35; whilst the remaining 8 prizes were awarded to silage compressed by mechanical pressure silage pressed by the system of chain pressure introduced and patented by Messrs. Reynolds & Co. engineers, Blackfriars-road, London, taking no less than five, although only 34 using this pressure were in competition it would thus be seen that out of every 34½ competitors using Messrs. Reynolds' mechanical pressure one received a prize. Whilst mid the dead weights and other mechanical pressure only one in 10/15 was successful.

In most cases dead weights were of bricks, planks, pig iron, concrete blocks, and in bags or barrels, billets of wood, or simply dry earth. Mr. Swan, the first witness called, and winner of the champion cup at the Show, weighted his ensilage with bricks. Mr. Hardy, of Weedon, used Reynolds' and Co.'s chain system, and believed it cheaper than any appliance of dead weights. Mr. Woods, at Merton, in using rough farm-made boxes of wood filled with stones, applied 70 lbs. to the foot, believed the cheapest and

most effective pressure was obtained. A great number of devices has been adopted to give the supposed necessary pressure. A foot of plain sand direct on the forage at Shrewsbury was found satisfactory, as in many other notable instances. The cost of a silo naturally is very different—7s. 6d. to 30s. per ton of space—and cannot here be specified in detail.

D.—Most silos appear to have been built by occupying owners, and a large proportion by the conversion of old buildings. But jointly, at owners' and tenants' expense, the silo accommodation of the country is increasing, while some tenants are making their own silos with materials, such as the concrete slabs of Messrs. Lascelles, which can be removed and remain of good value for other purposes. The materials used include bricks, concrete, wood, iron, slate, &c.

E.—The names of crops, put into silos, cover most of the produce of the land, grass representing quite one-third of the total; next come clover and rye. Clover, maize, rye, beans, oats and peas sainfoin, tares, trifolium, buckwheat and hop-bines, spurrey, cabbage, and mixed crops have all been successfully preserved. The right stage of ripeness of the crops is fairly established in most cases, farmers and chemists being here in agreement.

F and G.—Refer to costs of chaffing crops and where such process is desirable. Here the balance of evidence favours chaffing, but in the case of meadow hay much excellent ensilage has been made from unchaffed grass. The records of temperature are very imperfectly given, and on this important point further information is desired. The ensilage made at Merton, where the temperature does not usually exceed 50 deg., was of the finest character, but yet sweet ensilage, like that made by Mr. Howard and many others, remains excellent food after exposure to a temperature of 120 to 150 degrees.

H.—Replies to this question show the super-silo is not often used; that shrinkage after pressure is very various, from a fourth to a half of the bulk, and that after the first fortnight very little shrinkage occurs.

I and J.—Offered the moot point of extra costs in carting green forage as against dry hay, and *per contra* the costs saved through not having to make hay. The answers are not decisive, but the balance of testimony is that making ensilage is less costly than making hay, even in ordinary weather.

K.—Is a question as to dates of filling and opening, &c. The evidence indicates that at any time after two months from the filling, the siloed crops are available for feeding, and will remain good for over a year.

L.—Rations for fattening stock, for cows in milk, for store cattle, for sheep, for horses, are used in very different quantities. Apparently, as reasonable, ensilage is of most value as a mixed food.

M.—Elicited reports of experiments on fattening cattle, showing ensilage about equal to the best other food, and for cows in milk and ewes in lambs as superior to most other winter provender.

N.—The evidence was in favour of ensilage for its effects on the yield of milk in quality, taste, and quantity. The testimony of Mr. Sparks in reference to the condensed milk factories refusing milk from ensilage-fed cows was to the effect that, in view of exporting large quantities that had to be kept for long periods, the management simply acted with precaution in waiting to learn from experience the effects of feeding on ensilage; while their demand for milk from cows fed on old systems was amply supplied. Mr. Barham witnessed to the good character of the thousands of gallons daily received of milk made from ensilage cows. It seemed to be preferred by the customers of the Dairy Supply Company.

O.—The health of the stock fed on ensilage appears to be affected in a few cases unfavourably, but much more often advantageously, and probably increased experience will enable farmers and dairymen to make ensilage valuable as an health agent as well as a food for their stock.

P.—Scarcely any witness offered an opinion as to the value of manure from feeding a ton of ensilage as compared with the value of manure from a ton of roots. According to ordinary formula, the product should be quite double in favour of ensilage, manure from feeding hay being much better than that from feeding roots.

Q.—Produced but one direct answer as to the value for the silo of an acre of green wheat. The estimate was £6, plus the saving of hoeing and weeding the crop.

R.—Referring to analyses and feeding experiments elicited returns mostly in writing, as documentary evidence.

S.—Was a crucial point, asking whether the produce of an acre of forage made into ensilage was of more or less value than the same produce made into hay. The replies generally will be found in favour of ensilage, nor is the evidence of Sir John Lawes on this point opposed to the other witnesses.

T.—May be reckoned as establishing the present position of the ensilage process as satisfactory. Most of the experimentalists were satisfied with the present silos and appliances, and in view of building fresh ones, only suggested trivial alterations.

U.—Referring to the stacking process, received but very attenuated evidence, but its desirability was evident, and the present season will afford ample evidence as to the economy of making ensilage without a silo, a £25 prize being offered by the Royal Agricultural Society of England.

V.—Introduced the discussion as to the desirability of making sweet or sour ensilage, the verdict of which has yet to be given by the chemists. The dividing line between the two is not drawn; and undeniable witnesses assert both sorts of ensilage are good; cattle and other stock thrive on either.

W.—Asked if ample silo accommodation existed, what would be the system of cropping to be recommended, but any definite opinion was not received.

The remaining points, as to preservation and storage of grain in silos, as to the methods of making ensilage forage marketable and available for town dairies, were adverted to by some witnesses without affording the Commissioners grounds for any definite conclusions, judging from their preliminary report.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, NOVEMBER 28, 1885.

[No. 48.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 11TH NOVEMBER 1885.]

Madras.—General prospects fair; continue favourable in Bellary and Anantaporo.

Bombay.—River still falling in Sind; slight rain in parts of fourteen districts; more rain required for *rabi* crops in one taluka of Nasik and in parts of Khandesh. Reaping of *kharif* and sowing of *rabi* crops nearly completed in some districts; in progress in others. Cholera in parts of eight; fever in parts of fifteen; cattle-disease in parts of eleven, and small-pox in parts of four districts.

Bengal.—Some rain fell in Orissa and in Singbhoon and Manbhoon; cold weather is setting in. Prospects of rice crops are generally very favorable, except in the flooded tracts previously reported, and in South Behar where want of later rain has done harm; *rabi* crops are being largely sown, but in Behar *rabi* and poppy sowings are backward for want of rain. Price of rice has fallen in almost all districts. Public health generally fair.

N.-W. P. & Oudh.—Weather getting cooler. *Rabi* sowings in progress everywhere and prospects said to be good. Markets are well supplied and prices on the whole steady. General health fair.

Punjab.—Fever in the Delhi and Peshawur districts, in the Kahuta tahsil of the Rawul Pindoo district, and in the Dohra Ismail Khan city, also a few cases of cholera in the Dohra Ismail Khan district; health otherwise good. *Kharif* harvesting nearly completed; *rabi* operations in progress. Rain is much needed. Prices rising in the Ferozepore, Unritaur, Sialkot, Lahore, and Shahpore districts; stationary elsewhere.

Central Provinces.—Weather cloudy and close. Prospects continue favourable. Fever prevalent in a few districts. Prices steady.

British Burmah.—Cholera slight in five districts; elsewhere public health good; cattle-disease slight in six districts; elsewhere health of cattle good. Crop prospects good except in Thayetmyo, Bassein, and Prome, where rainfall has not been sufficient.

Assam.—Weather seasonable; mornings foggy. *Kharif* seems to be still lingering here and there in Luki Tehsil. Mustard being sown. The *silk* paddy has been injured here and there by insects; state of other crops and prospects good. In some parts of Cachar partly destroyed by insects; tea-plucking will soon cease. Common rice 13 seers 15 chittacks per rupee. Public health good.

Mysore and Coorg.—Standing crops in good condition; recently sown *rabi* in the Bangalore districts is reported to be in need of a few more showers of rain; prospects of season and public health generally good, cattle-disease still prevails in parts of the Malnad district. Prices have slightly risen except in the Tumkur district, where they were reported to be falling. Prospects of season and public health good.

Barar and Hyderabad.—Weather close in Omraoti, where cotton-picking continues, *rabi* sowing nearly completed, wheat 22 and jawari 26 seers per rupee. *Kharif* crops in good condition in Akola, where *rabi* sowing progressing. The rainfall in Hyderabad has damaged *rabi* and *kharif* crops to some extent and breached many tanks. General health fair, except in Shahabad taluka, where fever prevails. Prices—Wheat 13, coarse rice 12½, yellow *juar* 23½, white *juar* 19½, and tur 15½ seers per current sicca rupee.

Central India States.—Cholera in town of Rewah, 24 cases, 15 deaths. Weather cooler. Sowing of opium, gram and wheat in progress. Health and prospects good. Ploughing and *rabi* sowings commenced in Nowgong, where prices falling. Sowing operations almost finished in Manpore.

Rajpootana.—*Rabi* sowings commenced and in progress. Weather dry, cool at nights. *Kharif* crops have been cut in Meywar, where prices rising and fever prevalent. *Juar* ripening; tanks and wells drying in most places. Rain needed everywhere. Health fair. *Kharif* crops injured in Kerowli where fever prevalent, and prices rising. Prices stationary in most places.

[FOR THE WEEK ENDING 18TH NOVEMBER 1885.]

Madras.—General prospects fair continue favourable in Bellary and Anantaporo.

Bombay.—River low in Sind. Rain in parts of nine districts, more required in parts of Poona, Nasik, Ahmednuggar, and Khandesh. Reaping of *kharif* and sowing of *rabi* crops continue in most districts. Standing crops damaged by insects in parts of Panch Mehals and by blight in parts of Satara. Cholera and small-pox in parts of six, fever in parts of twelve, and cattle-disease in parts of nine districts.

Bengal.—Rains have ceased, and cold weather has set in. Outside the flooded tracts, and except in parts of Behar where some harm has been done by the failure of rain in October, the rice crops generally promise an excellent harvest; cultivation of *rabi* crops and *bora* paddy is proceeding well, but in Behar want of rain somewhat interferes with *rabi* and poppy sowings; harvesting of earlier sorts of *amra* rice has commenced; the price of rice has consequently fallen in several districts. Public health continues generally fair.

N.-W. Provinces and Oudh.—Weather seasonable; *rabi* operations still in progress; in some places completed. Prospects are said to be good and prices generally steady. Public health is fair; cholera and fever continue in a few districts.

Punjab.—No rain; it is much needed. Fever in the Delhi and Peshawur districts, in the Kahuta and Attock tahsils of the Rawul Pindoo district, and in the Dohra Ismail Khan city; cholera in the villages of Kulachi, Gumal, and Mularjal in the Dohra Ismail Khan district; elsewhere health is generally good. *Kharif* nearly harvested; *rabi* operations in progress. Prices rising in the Unritaur, Sialkot, and Shahpore districts, falling in the Rawul Pindoo district, and generally stationary elsewhere.

Central Provinces.—Cold setting in. Prospects continue favourable. Fever and cholera in places. Prices steady.

British Burmah.—Cholera slight in three districts; elsewhere public health good; cattle-disease slight in five districts; elsewhere health of cattle good. Crop prospects good in all districts except in parts of the Prome and Thayetmyo districts, where the rainfall has not been sufficient.

Assam.—Weather seasonable. Public health fair. State and prospects of crops generally good. Tea-plucking will soon cease. Common rice 14 seers 8 3/5 chittacks per rupee. In Debrugurh the prospects of tea, sugarcane, *metilalai*, and other crops good.

Mysore and Coorg.—Rain fell more or less abundantly in the Malnad district, and slightly in parts of the Malnad Taluka of the State. In the Tumkur district and in parts of the Bangalore district late sown crops are reported to be in want of more rain, otherwise standing crops in good condition. Prospects of season favourable. Public health generally good; small-pox at some places. In Tumkur and Shimoga districts drinking water and pasturage available. Cattle in good condition, except in parts of the Shimoga district where murrain still prevails. Prices in the Tumkur district reported stationary, elsewhere have fallen. Coffee crops being picked. Prices of food-grains slightly risen in Mercara.

Barar and Hyderabad.—Weather clear and cool. Prospects favourable. Second picking of cotton in progress. Wheat 22 and *juar* 26 seers per rupee in Amraoti. *Kharif* harvesting commenced; *rabi* crops progressing favourably. Break in weather proved beneficial to standing crops; *rabi* sowings continue. Fever prevails in some places. Prices—wheat 13, coarse rice 12½, white *juar* 19½, yellow *juar* 23½, and tur 15½ seers, per current sicca rupee.

Central India States.—Weather cooler and seasonable. Health and prospects good. Cholera decreasing in Itowah; 9 cases of cholera, 6 deaths. Weather seasonable. Crops doing well. Health good. Total rainfall 41.17; heavy hailstorm on 12th. Prices falling; sowing operations finished; opium sowing commenced.

Rajpootana.—Fever still continues; otherwise general health good. Crops being gathered in Mewar. Prices tending to rise. Tanks and wells fair in Sirohi, Kerwara, Marwar, and Bhurtipore, *rabi* sowings about to commence in some places and in progress elsewhere. Tanks and wells decreasing in parts. *Kharif* crops being harvested and *rabi* sowings actively carried on in Bhurtipore. Prices rising in some parts and stationary in others. Prospects fair.

Letters to the Editor.

FISH MANURE FOR TEA GARDENS.

TO THE EDITOR.

SIR,—A correspondent of yours, writing "from his own experience," recommends the application of fish manure to tea-plants. Will he kindly say—

1. How much does it cost to fish-manure 50 acres of tea?
2. What quantity is to be applied per bush or per acre?
3. Where is this fish manure to be obtained from?
4. Where is the garden in which your correspondent applied fish-manure to tea-plants?

AN INQUIRER.

Editorial Notes.

In another column will be found an analysis of the American corn crop for 1885, which shows that, notwithstanding the bad season, it is estimated to exceed the last year's crop by 187,200,000 bushels.

LATEST advices state that the Melbourne tea market is active at ten per cent reduction on China teas. Good sales of Indians and Ceylons are reported, and the landings are heavy. Stocks are increasing, the recent quality having met with approval.

In another column will be found two interesting papers on Coca, taken from the *Chemist and Druggist*. The one furnishes particulars as to cultivation, drying, and statistics as to produce at the source of supply, and the other the results of experiments with the hydrochlorate of cocaine as an anæsthetic.

THE *Pioneer* has noticed at some length the annual statement of the wheat crop published by Sir J. B. Lawes. The report is of value, inasmuch as agricultural observations have been continuously made on Sir J. B. Lawes's experimental farm at Rothamstead for 42 years. The review will be found elsewhere.

We understand that the agricultural loans advanced in the Moorsheadabad District on account of the recent floods amounted to Rs. 16,532. The Relief Committee distributed Rs. 3,500, and have still Rs. 1,289 in hand. The works on the roads employ 1,200 persons, and the Collector reports that "all classes seem to be contented."

THE total quantity of tea exported from China and Japan from the commencement of the season to the 27th of October, amounted to 118,113,895 lbs., as compared with 120,278,493 lbs. during the corresponding period of last year. The exports to the United States and Canada during the same period were 55,387,482 lbs., as against 53,355,069 lbs.

At the request of the Revenue and Agricultural Department of the Government of India, Mr. H. Caine, of the Poosa Farm, has drawn up a memorandum which will be found elsewhere, regarding the method employed at the Farm for cultivating, preparing soil, sowing, planting and treatment of tobacco while growing, for the information of the Superintendent of the Andamans and Nicobar Islands.

THE Government of Madras have approved of a proposal to hold an Agri-horticultural Show at Rajamundry this year, similar to the one held last year, towards which a contribution of Rs. 500 will be made by Government. The show of 1884 was pronounced a success, and we hope the management will be equally successful this year. It is calculated to cost Rs. 2,440.

We notice the appointment of Mir Mahomed Hussain to be Assistant Director of Agriculture and Commerce in the North-West Provinces. The post has always hitherto been filled by a covenanted civilian or military officer. Mir Mahomed Hussain owes his elevation not only to his success at the Cirencester Agricultural College, but to his practical aptitude since displayed in the Agricultural Department of the North-West.

From the statement showing the annual forecast of the Cotton crop in the Hyderabad Assigned districts for the season 1885-86, it appears that the area under cotton falls short of the previous year by 6·6 per cent. The reason for this is said to be the want of timely rainfall; but a 12-annas outturn is nevertheless estimated, which is warranted by the healthy appearance of the plants. On this basis, the crop of the year is estimated at about 20 per cent over that of last year, the probable yield being put at 490,000 cwts.

THE report on the rice prospects of British Burmah for October 1885 is as follows:—

"The area under rice is now reported as 191,936 acres above last year's area, giving an increase of 6·2 per cent. The rainfall has been favourable in October in the lower districts of the delta, but in Henzada, Promo and Tharrawaddy the rainfall was not sufficient, and a light crop may be expected in these districts, unless they get more rain at an early date. In the other districts the crop prospects are reported to be very good."

THE *Chicago Tribune* publishes the following figures as representing the annual cost to the people of the United States in intoxicants and tobacco:—Alcoholic liquors, 546,000,000 dls.; malt liquors, 306,000,000 dls.; tobacco in its various forms, 292,000,000 dls.; total, 1,138,000,000 dollars. This is equivalent to 20 dls. per head of the entire population, and to two-thirds of the present national debt. The *Tribune* does not think it can be claimed that this is all wasted, as a large proportion of it is paid in wages to producers and manufacturers, or as revenue to the national and local governments.

THE services of Mr. Havell are to be placed at the disposal of the Madras Revenue Department for deputation upon special duty, for the purpose of making a tour of inspection in the northern districts of the presidency, and collecting information as to arts and manufactures existing in those districts. The Director has suggested certain arts and industries for investigation, and has drawn up a list of such as may with advantage be examined by Mr. Havell. We should have an interesting report by Mr. Havell shortly.

THE Resolution of the Government of Bombay shows that Irrigation is advancing with rapid strides in that presidency. The area for which irrigation from the Government canals and tanks was applied for from the beginning of the *khurif* season to the 15th October this year was 29,865 acres, as compared with 21,833 acres for the corresponding period of 1884 and 17,566 for 1883. Of the increase of 8,022 acres, as compared with last year, 2,952 acres are allotted to the New Canal, which was opened on the 15th June 1885, and the rest, viz., 5,070 acres, are made up of general increase on almost all the other works. Except in Guzerat, the increase was not due to deficient rainfall, and is regarded by the Government as satisfactory.

"PINK BETTER" is to be the name of all compounds made in imitation of butter in New Hampshire. The *N. E. Farmer*, an American paper, says on this subject:—

"Hereafter all oleomargarine, or articles or compounds made in imitation of butter, and sold or offered for sale in the State of New Hampshire, must be colored pink; no other color or shade whatever will pass muster, and if any unfortunate manufacturer should happen to get his goods colored a little too highly, say to a crushed strawberry tint, in his honest desire to make them pink enough to answer the stern requirement of the law, we presume he would be in danger of having to pay the fifty-dollar fine. Why not have a legal standard of pinkness, to be kept by the local dealers of weights and

measures, and also a further provision for the scientific testing of juremen for color blindness?"

The *Farmers' Review*, another American paper, comments as follows on this question:—

Decidedly a good idea, provided the courts do not pronounce it unconstitutional. If all imitations of butter could be required to be of a distinctive color, unlike the genuine article, the dairy man could then well afford to submit to the competition with them. Since such compounds are all artificially colored, why not provide by law that they shall be of a color unlike that of genuine butter? This would do away with all fraud in their sale to consumers. We shall watch with interest the practical operation of the law in New Hampshire.

If a distinctive feature of this kind is wanted anywhere, it is in India—especially in Calcutta, where the most nauseous compounds are passed off as butter.

ONE of our American exchanges tells us that the phosphatic rock deposits of South Carolina are now the principal source of supply of the phosphate of lime used in the manufacture of commercial fertilizers throughout the world. The district underlain by them, of which Charleston is about the centre, is some seventy miles in length by thirty in breadth, and the supply is considered to be practically inexhaustible. It crops out at the surface in some places, and in others is overlaid with soil to a considerable depth. The State levies a tax of one dollar per ton on all that is shipped, making quite a source of revenue, since the production last year was about 500,000 tons, and is yearly increasing to meet the increased demand for it.

THE following is the second report on the prospects of cotton in the Bombay Presidency for 1885:—"Sind returns not received. Gujarat, British districts:—revised area 600,000 acres or 50,000 acres above average; Native States, returns incomplete; prospects improved. Deccan (excluding Khandesh):—Satara above average 16,000 acres, Nagar, Sholapore, Nasik, and Poona much below average, last two far below last year; total area 42,000 acres against average 125,000 acres. Khandesh:—682,000 acres or 200,000 below last year and 125,000 acres below average; late rains have improved the crop. Southern Mahratta Country:—sowings late: Dharwar 375,000 acres, Belgaum 125,000 acres, both up to average; Bijapore 150,000 acres average 275,000 acres, rains deficient. Estimate for Kolhapore and neighbouring State 150,000 acres; young crops healthy."

THE Madras Government have recently sanctioned a proposal made by the Director of Agriculture to spend a small sum during the current year on a ploughing competition to be held in the Kurnool district during this month. Among the reasons assigned for selecting Kurnool for this purpose, it is stated to be one in which the "sign of progress," pointed to by Government in April 1884, may very probably be exhibited, i.e., says the Director, "it is quite likely that ryots may, using improved ploughs drawn by their own cattle and held by their own men, compete against their neighbours using the country plough." The Government, in conveying sanction have observed that, although an allotment of Rs. 200 is available for "the exhibition of improved ploughs and machines," no allotment has been provided for ploughing competitions. The small sum required will, therefore, be provided from savings.

THE report of the indigo brokers is that nearly half the crop of native Ondha has already arrived in the market, but that proprietors are holding out for very high rates. Packing is going on busily in Bengal and Tirhoot, but it is expected to be at least a fortnight before a good supply from these quarters comes to market. Most of the boiling samples from Bengal and first castings from Tirhoot have arrived. The former are said to be fully up to the average, and some even very superior; whilst the latter are of average quality, but contain no very fine samples. The *khantees* are said to be decidedly inferior, owing to the unfavourable manufacturing weather. On private sale the Baromasea, Moorsheadabad, factory, have obtained at Rs. 300 per maund, for 320 maunds, with the usual rejections.

THE following experiments by Mr. M. A. Lawson with coca leaves will be read with interest:—

The uses to which cocaine has been put in surgery by the Faculty has rendered it desirable to test the amount and nature of alkaloid from plants grown in India. Some leaves which had been carefully dried in the shade from trees in Barliyar havo, on three occasions, been analysed by me. The first sample was examined by Trompeter's method; it yielded 2 per cent of an alkaloid which gave no characteristic result of physiological action. The second sample was treated according to Castaing's method, and gave about the same amount of alkaloid, which produced distinct numbness on the tongue, but Dr. Drake Brockman of the Eye Infirmary, Madras, reported that it produced a smarting when applied to the mucous surface. A third sample had been tested by Dr. Squibb's process which afforded 50 per cent crude alkaloid and 30 per cent cocaine hydrochlorate. This had a very marked numbness on the tongue, and has been sent to Dr. Brockman who has kindly promised to report upon its value.

OUR Ootacamund contemporary, who is an authority on all descriptions of planting, observes that it is always extremely difficult to estimate the probable quantity of cinchona bark that may be exported from this country in any one year. The price at home, if high, stimulates production; if low, it has a contrary effect. A planter finds that delay in harvesting cinchona bark has not the same effect as with tea or coffee. With tea a flush must be picked when it appears or it is lost, so with coffee the fruit must be gathered when ripe or loss will ensue, but in the case of cinchona, delay has the effect of improving the crop, and the quotations of the market at the moment are all powerful factors in the outturn. If these quotations are good, a considerable output is the result: if bad or indifferent and the planter can afford to wait, exports fall. There is just now a slight rise in the market for cinchona bark at home, and we may look for some activity in harvesting, but 6½d a unit will never prove remunerative for the bulk of growers, who have only branch and twig bark to dispose of, and trunk bark from trees yielding a low percentage of sulphate of quinine.

A CONTEMPORARY notices with regret that the Government should remain so persistently passive and indifferent to the important subject of developing the mineral resources of various tracts of the country in Southern India (more especially the Wynad), leaving it to the enterprise of private capitalists either to make or mar the mining industry which, if successfully established, would gladden the hearts of shareholders and compensate them for the investment of their capital and the patience they have exhibited; while on the other hand, the country itself would be enriched, and the now much depreciated rupee would revert to its original value. Our contemporary goes on to say that in Hyderabad, the Nizam's Government is making strenuous efforts to develop the mineral resources of that part of India, and has entered into arrangement with a firm in England with this object in view. In Mysore the gold-producing character of the country cannot be doubted, and the last returns yielded fully realise the best expectations. The Devala Moyar Mines, which are cited as examples, are said to be almost paying expenses, and it is confidently asserted that a much more satisfactory result will soon be obtained; but yet, in the face of all this, the Government stands aloof, and will make no effort to assist private enterprise.

THE digestibility or otherwise of cheese is a question upon which very diverse opinions exist. By some it is maintained that cheese should be eaten before meals, by others that it should not be partaken of unless after meals, with a view to assist digestion. There are those again who hold that it should be eaten with the regular meal. In this country we believe, it generally forms the last course of a meal, from which it may be inferred that it is regarded more as a condiment than anything else, and is believed to assist digestion. We have always thought that cheese was more or less harder of digestion than ordinary food. This would appear to be an erroneous conclusion, according to the experiments carried out by an eminent German chemist, Von Klunge, who undertook

to determine the digestibility of different samples of cheese with the results given below. He was of course obliged to conduct his analyses with artificial gastric juice, and the figures obtained show the percentage of the total proteins or caseine which was digested or dissolved, and which may be taken as representing the relative proportions of their substance taken into the system for assimilation and nutrition. The list of tests was—

Emmenthal, first quality	97.5
Emmenthal, second quality	92.3
Romadour	94.
Gorgonzola, second quality	94.4
Mainz, hand cheese	93.
Cheddar, second quality	91.6
Roquefort, fresh	90.9
Brie, second quality	87.3
Neuchâtel	85.6
Swiss skim-cheese, fresh	77.1
Swiss skim-cheese, old	90.2
Meat, cooked with butter	97.5
Eggs	97.4
Milk	91.7
Milk, with cheese	96.2

.

An American journal commenting on these results, says :—

It will be noticed that of two qualities of Emmenthal cheese, the better one is the most digestible, because it contained 2.5 per cent more fat. The Brie and Neuchâtel stand much lower in digestibility than even a second quality Cheddar, and the Cheddar is lower than the odoriferous Linburg. The favourable effect in ripening, in increasing digestibility, is seen in comparing the fresh and old Swiss skim cheese, where ripening greatly increases the value of the skim cheese. Comparing cheese and other kinds of foods rich in proteins, it is seen that the opinion that cheese is a particularly indigestible form of such food is not well founded, provided it is good in quality and well ripened. This experiment shows that the proteins or caseine is as completely dissolved as is the proteins or fibrine of meat or the proteins or albumen of eggs, and much more so than when the same caseine is taken in fresh milk. In order then to do away with the widespread prejudice against the digestibility of cheese that prevails in America, or at least in the United States, the cheese-maker for home consumption should not only make a cheese rich in fats, but he should have it well ripened before sending it out for consumption.

.

MR. L. B. ARNOLD, in a letter to the *National Live Stock Journal* on this subject, says that in 1878 and 1879, he, associated with Dr. F. E. Englehardt, of Syracuse, N. Y., made large numbers of experiments on the digestibility of every kind of cheese they could obtain. The results, it is said, did not differ materially from those since obtained by Von Kluge and which we have quoted above. He found that "cheese well cured and containing all the butter fat of the milk" was more digestible than green, or partly cured, or skim cheese, and that the skims were not so valuable for food in proportion to price as full cream cheese. In fact that, cheap skim cheese was dearer as an article of food than rich full cream cheese at its full price. Meat, eggs, and milk bear almost the same proportion of digestibility as cheese, and that of the three first-named milk was found to be the least digestible. The old opinion then, which has been maintained for so long by some of the most distinguished chemists of the age, that milk and eggs formed the "most perfect food," must be somewhat modified; for according to Von Kluge, meat cooked with butter gave the same results as first quality Emmenthal cheese, and the percentage of digestibility exceeded that of pure milk by 6. This is somewhat in variance with the hitherto accepted conclusions.

.

Among the large quantity of indigenous gums and other vegetable substances sent to him for examination, Mr. M. A. Lawson notices the following :—

Moringa Gum.—The gummy exudation of the horse-radish tree (*Moringa pterygosperma*) consists chemically of a large quantity of bassoria or insoluble gum with a small proportion of arabin or the soluble kind and a trace of moringa-tannic acid. It swells up to a remarkable extent when steeped in water, gelatinizes with ferric chloride, gives an abundant precipitate with subacetate of lead,

and is soluble in caustic alkalies. In these and other respects it resembles the Gum-Hogg of America. Gum-Hogg is derived from an unknown source and imported from the East Indies; it is used in marbling paper for binding books. It seems not improbable that Moringa gum, if not identical with it, could be used for the same purpose in the arts.

The funicles of the Black Wattle (*Acacia melanoxylon*) are in the shape of pink contorted bands, and were supposed to contain a dye. They were free from starch and tannin and yielded 6 per cent of moisture and 2 per cent of ash. Their chief constituent is an albuminous matter similar to the white of an egg. About 30 per cent is readily extracted by macerating the funicles in water. When this solution is heated, the albumen coagulates and the pink coloring matter is destroyed. Being of no use as a dye, their peculiar office seems to be that of affording nourishment to the seed.

Deposit from the milky secretion of the Jack fruit (*Artocarpus integrifolius*).—This was a thick white tenacious substance similar to bird-lime, with no marked odour and taste. It contained 20 per cent water and the residue burnt with a bright flame giving off a sooty smoke. It was insoluble in water, partly so in alcohol, and entirely in benzol. It was a variety of caoutchouc, and as such would be useful as a bird-lime, and a cement for broken articles.

.

An Australian paper, the *Queenslander*, publishes some interesting particulars regarding the manufacture of orange-wine. It says :—

Some time ago in the Querists' column of the *Queenslander*, the subject of making wine from oranges was mooted. In response to our request for practical information, a vine-grower and wine-maker, who has within the last few years visited many of the European continental vineyards, called upon us. He informs us, and wishes the fact to be made widely known, that a most excellent wine can be made from the juice of the orange and that since the troubles caused by the phylloxera, a large proportion of the "sherry" of commerce is orange-wine. Moreover, when properly prepared, he says, this orange sherry is a most pleasant and healthful wine; indeed in his opinion it is only a matter of a few years, and the greater part of the wine in the world will be made from oranges, for the product is equal to that made from the juice of the grapes, and the yield per acre considerably more. His argument is that in consequence of this discovery, the planting of orange groves in suitable localities in Queensland cannot be overdone. As endorsing these conclusions, in the Melbourne *Leader* we find the following paragraph :—"It is stated the manufacture of orange wine is developing into a very extensive business in Florida, where a magnificent American wine is being made in large quantities from the juice of the sweet oranges, surpassing in purity any of the European wines. 'It is said to be the best tonic, medicinal or otherwise, that can be taken in the human system. It is nourishing, of agreeable flavour, and, what is more, a perfectly pure native wine.' No part of the fruit is used in the manufacture of the wine but the pulp of the perfectly ripe oranges, and none of the wine bottled from the casks until it is at least three years old. In taste, it is marvellously palatable and contains but 8.64 per cent of absolute alcohol and slightly over 5 per cent of sugar. Florida, filled with orange presses, says the Philadelphia *Times*, will outrival the famous vineyards of France and Italy in time, for the manufacturers of this splendid wine are pushing ahead with new and improved machinery, are setting out countless orchards of the precious fruit, and investing thousands of dollars in the enterprise, which they are satisfied will soon become one of the greatest industries of the country. The supply now is no ways equal to the demand."

.

It is not perhaps generally known that Assam contributes largely to the cotton trade of India. In the absence of accurate statistics it is difficult to arrive at a correct calculation of the total area under cotton, but it has been estimated to cover 38,815 acres, exclusive of the Naga hills. Of this about 7,000 acres are situated in the plains districts, and the remainder in the Garo, Khasi, Jaintia, and north Cachar hills, the largest proportion being in the Garo hills, where it is estimated at about 22,823 acres. Occasional patches of cotton occur in the plains, where the Miris grow a limited crop for their own use in the district of Lakhimpore and Sibsagar. On the lower slopes of the Bhootan hills cotton was once said to have been extensively grown, and Kamroop was famous for it. But the trade has now decreased considerably, though in certain areas of the Khasia hills, in the Kamroop district, *ghuming* is still carried

on to a limited extent. In the Goalpara district about 1,800 acres are under cotton, but this is confined to the Silli and Bijni pergunnas. The chief cotton-growing district in the Assam Valley would appear to be Nowgong, in which the Mikir hills are included. The area under cotton here is estimated at 3,286 acres. The Sarma Valley has about 1,400 acres under cotton, confined principally to the Sylhet and Cachar sub-divisions. The latter, however, does not include the hill Cachar hills, where cotton occupies about 4,000 acres, and is largely exported as well as used for local consumption by the hill Cacharies, Nagas, and Kukis. In the range of mountains which extends from the head of the Brahmaputra Valley to the confines of Mymensingh, cotton forms nearly everywhere the staple crop, and large quantities are annually exported to Kamroop, Nowgong and Sibsaur.

It is stated by a contemporary that, at the request of the principal mercantile firms in the Central Provinces, the Chief Commissioner has decided to make an attempt to substitute weighment for measurement in the grain markets of those Provinces. As is not unusual in this country, there is a great diversity in sizes of the different measures at present in use in different markets. Of course it might be possible to substitute one single general measure of capacity for use locally; but this would only partly meet the difficulty, as the grain is sold by weight in Bombay, and its carriage charged for by weight by the Railway Companies. Another difficulty, which will not be met by the introduction of standard measure, is that the grains, especially wheat, vary very much in weight according to their different kinds and at different seasons of the year. The new weight to be adopted as the standard will be the seer of 80 tolahs, which is the weight on which the Great Indian Peninsula tariff is based, and which is already experimentally in force in the markets of Jubbulpore and Kampti. Mr. Crosthwaite now purposes to introduce the new system of weighing in the markets of Kareli, Gadawara, Hoshungabad, and Hurda, to be managed, if possible, by licensed weighmen under the orders of the Municipal Committee, whose co-operation is to be invited. A supply of the proposed new weights is shortly expected, when they will be issued from the office of the Director of Agriculture to Municipal Committees, in sets of five, consisting of one weight of five seers, one of two seers, one of one, one of half a seer, and one of a quarter seer. Sets of weights will also be given free of charge to every trader or weighman who brings in exchange a *kuro* measure, or one representing the *kuro* in capacity, and they will be sold to the public at the rate of Rs. 2 a set. It will be no doubt a great convenience to the public if this reform could be carried out, but the Chief Commissioner will find considerable difficulty in dealing with the matter.

THE following is the report on the state of the season and prospects of the crops for the weeks ending 11th and 18th November 1885:—Good rain has fallen in the Madras Presidency during the last fortnight, and agricultural prospects are now good everywhere. In Bellary and Anantapore the condition of the crops continues to be favourable. In Mysore, where there was a fair amount of rain, the prospects of the season are favourable, and the standing crops are in good condition, except that in parts of the Tumkur and Bangalore district more rain would be beneficial. In Coorg prospects continue good. In the Bombay Presidency there has been rain in several districts during the fortnight under report. The reaping of the *kharif* and the sowing of the *rabi* crops continue. In the Berars the *kharif* harvest has commenced, and sowings have been resumed in the Nizam's Territories, owing to the break in the rains which has been beneficial to the crops. Prospects continue good in the Central India States, and *kharif* harvest and *rabi* sowings are in progress in Rajpootana. In the Central Provinces, slight rain fell in two or three districts and prospects continue favourable. Rain is much needed in some places in the Punjab, where none has fallen during the fortnight under notice. The *kharif* harvest is approaching completion, and the *rabi* operations are in progress. Seasonable weather prevails in the North-Western Provinces and Oudh, where *rabi* operations are still in progress, and have been completed in places. Agricultural prospects are good. In Bengal the rains have ceased, and the cold weather has set in.

Outside the flooded tracts and parts of Behar, the rice crop promises generally an excellent harvest. The cultivation of *rabi* and *boro* paddy is proceeding well, and the harvesting of the earlier sorts of *aman* rice has commenced; but in Behar *rabi* and poppy sowings are backward for want of rain. In Assam agricultural prospects continue good. Crop prospects are good in British Burmah, except in the Prome and Thayetmyo districts, where there has been a deficiency of rain; the public health is generally fair. Prices are fluctuating in the Punjab and in Rajpootana, have slightly risen in Coorg, and are falling in Mysore. In Bengal the price of rice has fallen in several districts; elsewhere prices are generally stationary.

.*.*

A few weeks back we noticed the Arabian dye stuff called "waras," which is the product of a tree belonging to the natural order *Euphorbiaceae*. Mr. M. A. Lawson, the Director of cinchona plantations, parks and gardens, Nilgiris, in his report for 1884-85, gives an interesting account of this dye. He says:—

The resinous and powdery glands covering the pods of *Amorimia congesta* afford a very permanent dye, and much resemble in appearance the kamala of the Pharmacopoeias. A proximate analysis of this substance gave the composition as follows:—

Moisture	3.44
Resins	73.10
Matters soluble in water	8.20
Cellulose	9.60
Volatile oil	trace
Ash	6.03

Total 100.37

The coloring principle resides in the resin which is soluble in ether, alcohol, benzol, chloroform, and caustic soda solution. When a concentrated ethereal solution was allowed to stand for a day it deposited a mass of granular crystals, similar to those discovered by Doctor Anderson in "kamala" (glands from the fruit of an *Euphorbiaceae* plant). When the coloring matter of waras was examined side by side with that of kamala by means of a spectroscope, the amount of absorption was identical in each case, all the spectrum was darkened throughout except the red end which alone was visible. A dye-bath was made of the waras and pieces of cotton, linen, wool and silk were immersed. The color formed was that of a bright orange-brown, and the tint obtained was much superior in the animal fabrics as silk and wool, than in the vegetable tissues of cotton and linen. In these respects it resembles the dyeing properties of kamala. As a commercial undertaking, however, it would not be profitable to collect waras, as the amount obtained from the plants is so small in proportion compared with the yield of kamala.

.*.*

PRACTICAL and undoubted testimony is what, in our opinion, is wanted to prove beyond a possibility of doubt whether the ensiling of fodder does or does not improve its feeding value. The experiments of General H. C. Wilkinson have shown that it does; and as this was the only instance on record of the experiment having been conducted on thorough and scientific principles in India, we have no hesitation in accepting the General's conclusions as accurate. The investigations of the Royal Ensilage Commission in England have also established the superiority, in a more or less degree, of the feeding value of ensilage over ordinary fodder. In the last number of the *Farmers' Review* to hand, there is a letter from the pen of Mr. G. D. Foristall, farmer on the State Farm, Tewksbury, Massachusetts, addressed to the *New England Farmer*, in which he gives his "ensilage experience." He says: "The capabilities of ensilage feeding over the old methods seem almost incredible." The experiments were carried on uninterruptedly for four years, and the writer goes on to say that, after this long trial of ensilage feeding, the conclusions arrived at are these: "that it is capable of trebling the stock capacities of New England, and can be used with great advantage, either in dairying or beef production. For the latter, the stock have all the advantages of summer feeding with grain the year round. If any doubt this statement, I would like to have them visit the farm, and judge for themselves whether these things be so." For further details of his methods of ensiling, &c., we refer our readers to his letter, which we print elsewhere.

THE forecast of the Cotton crop of the Central Provinces for the season of 1885-86, promises well. Mr. Fuller, the officiating Director of Agriculture, says that cotton is only a crop of commercial importance over a very limited portion of these provinces, and no details have been obtained for this forecast from eight districts in which it plays quite an insignificant part. During the years 1883-84 and 1884-85, the cotton exported from these provinces amounted in value to 17 and 10½ lakhs of rupees respectively, and the proportions in which different parts of the provinces contributed to this export in the last-named year are roughly expressed by the following figures :—

Saugor, Damoh, and Jubbulpore	5
Nursingpore, Hoshungabad	11
Nimar	7½
Wurdha, Nagpore, Chanda, and Chindwara	12

Although an increase in the area is reported from most districts, Mr. Fuller takes occasion to remark that in estimating the character of this increase it must be remembered that its extent has been calculated on the areas of the preceding year, which were abnormally small, owing to the very unfavourable character of the season at sowing time. It is not believed, he says, that the area on which cotton is grown in these provinces, shows any tendency to permanent increase, while it is certain that in some tracts, noticeably in the Nagpore and Wurdha districts, cotton cultivation is giving place to that of linseed. The past season is stated on the whole to have been a good one for cotton, and estimates of out-turn below 10 annas in the rupee are probably under the mark. The rainfall at the end of June and commencement of July was not sufficiently continuous to hinder sowing, and there have been numerous breaks, during which weeding could be effected. The long break which continued throughout September may have harmed the crop in some places; but it is certain that cotton suffered from the deficiency much less than any other crop. On the whole an outturn nearly, if not quite, up to the average may be expected. In two districts, Nimar and Wurdha, the full average crop is expected, viz., a 12-anna crop. In two 11 annas, in three 10 annas, in two 8 annas, and in one 6 annas. From six districts no returns have been received, and apparently none are required, as cotton forms an insignificant crop in these.

.

THE officiating Director of Agriculture has issued the following forecast of the rice crop in the Central Provinces for the season 1885:—Rice production is of commercial importance only in the southern and eastern districts of the provinces. Although there is a considerable area under rice in the north-west corner of the provinces (including the districts of Damoh, Jubbulpore, Mandla, and Seoni), yet the amount of rice exported from this tract is relatively insignificant. In eight districts the crop is of such little importance that it has not been worth while to obtain a forecast of its out-turn from them. The area from which the rice exports of the provinces are chiefly drawn includes the Chanda, Bhundara, and Balaghat districts in the Nagpore division, and the three Chhattisgarh districts of Raepore, Bilaspore and Sumbulpore. The amount of rice which these provinces exported during 1884-5 was rather over 12½ lakh maunds, of which 3½ lakh maunds were subscribed by the Nagpore, and 8 lakh maunds by the Chhattisgarh districts. The opening portion of the past rainy season was favourable to rice, and in most districts a larger area was brought under crop, than bore rice in the preceding year. There were several good falls of rain during the hot weather months which were of great advantage, since they enabled cultivators to break up land before the regular rains commenced, and so give it a period of open fallow in the hot season. Up to the end of August prospects were everywhere exceedingly favourable, but a break in the rains commenced then which lasted in many parts for nearly two months, and was only interrupted by occasional very local showers. The rice crop of course suffered severely, and it is rather a matter of surprise that its present prospects are so good as they are reported. In many places the break commenced very shortly after the seedlings had been planted out, when damp weather is especially wanted; broadcast rice (under which class falls all that grown in Raepore and Bilaspore) fared better, but a considerable portion of the

crop on high lying ground will give but little return. Taking one district with another, the highest estimate which can be made is that of a two-third crop. The total area under rice in 1884 covered 2,980,291 acres. This exceeds the area under rice during the previous year by 40 per cent.

MAURITIUS SUGAR.

THE sugar industry has reached a crisis in Mauritius, and has called forth a paper by Mr. W. Newton, the President of the Chamber of Agriculture in that Colony, the object of which is to point out the dangers which threaten its sugar industry, and the measures he would suggest to remedy the depression of trade in general, and of sugar in particular. He takes a retrospective view of the question from the year 1878, when the English Antilles presented a petition to the Colonial Office, calling the attention of her Majesty's Government to the condition of inferiority to which the cane sugar produced by the Colonies of the English Antilles was reduced in relation to the beet-root sugar brought from France, Belgium, Holland, Austria, and Russia under protected bounties. He quotes valuable statistics showing the great advance the Continental beet-root sugars have made during recent years, and how prejudicially this has affected the cane sugar produced by the British Colonies, especially as the former were protected by foreign bounties. He refers fully to the remedy that has been suggested, viz., that the British Government should either enter into negotiation with the sugar-producing countries for the abolition of these bounties, or if this failed, should levy a countervailing duty on bounty-fed sugars equal to the amount of the bounties. But these proposals fell flat, and the Government were pledged to resist the compensating tax. Mr. Newton says that the crisis through which the island is at present passing may be defined as the struggle between the beet-root and the sugar-cane, complicated with the struggle between free trade and protection; and resolves itself into the question whether the cane is to capitulate to the beet-root. He points out the great superiority of cane sugar over that manufactured from beet-root, inasmuch as the former produces nearly twice as much sugar as the latter, from the same quantity of the raw material.

Mr. Newton's main object in addressing this paper to the Chamber of Agriculture is to rouse the people, particularly the planters and manufacturers, to a sense of the danger which threatens the sugar industry of the Colony. One of the chief remedies proposed by him is that the Indian Government should be asked to make it known as widely as possible, that no animal charcoal is used in the manufacture of Mauritius sugar, so that the people who are so largely ruled by religious prejudices may know that they can get Mauritius sugar at the same rate as other sugars, with the advantage that the former has no animal charcoal used in its manufacture, and for this reason ought to command the market in India. This point has been made known in India through the Madras Government. But Mr. Newton has overlooked one important point in this connection, viz., the cheapness of supply. As far as we can make out, the natives of India are not at the present time much influenced by this consideration, i.e., religious prejudices. Western civilization has done much to remove those religious scruples which a few years back ruled the consumption of foreign productions. Moreover, sugar factories are established in India itself, and animal charcoal forms an important factor in the manufacture of our white sugars. Some opposition was at first made to this, but recent years have seen this much reduced, and sugars manufactured with animal charcoal are as extensively used now, as they were excluded some years back. The consideration which mainly governs the Indian market at the present time (and sugar is no exception to the rule) is the cheapness of supply; and unless the Mauritius Government can offer advantages in this respect, there is little chance of their sugars finding the very ready market which they anticipate. Again, it must not be forgotten that India is a sugar-producing country, and that its export trade may yet assume proportions when, instead of being a sugar importing country, it will again become a sugar exporting country on a large scale.

TIL CROP, CENTRAL PROVINCES, 1885-86.

THE *Central Provinces Gazette* of the 14th instant contains a forecast of the Til crop for the season of 1885-86. Mr. J. B. Fuller, the officiating Director of Agriculture, sums up as follows:—

Speaking broadly, til represents the contribution towards the provincial exports which is made by the poorer classes of soil, and is to a great extent a speciality of hilly ground, on which wheat or linseed cannot be grown to much advantage. The tract in which most til is grown is the Nimar district, but as most districts in these Provinces include a considerable area of rocky land, til is a crop of some importance throughout the Provinces. Its commercial importance may be judged of from the fact that during the year 1883-84, its exports amounted to over 9 lakhs maunds, with a value of 34½ lakhs rupees, rather more than the value of the rice exported in that year.

The appended table contains a column which professes to show the area under til in each district during 1884-85—in thousands of acres. It must be remembered that, owing to the imperfect agency which has hitherto been at our disposal for crop registration, these figures are mere estimates, and I have given them more with the object of indicating the relative importance of different districts as til producers than with any idea of showing the actual area under til.

It will be noticed that the area now under til is very considerably in excess of last year's area. The increase is principally due to the fact that last year's area was abnormally small, owing to the continuous rain-fall having prevented sowings. Last year the til crop was a very small one, and the exports during 1884-85 only amounted to 2,80,781 maunds against 9,02,675 maunds in the preceding year. But there are also signs that the cultivation of til is gradually extending, and the Deputy Commissioners of Nimar and Wardha notice the effect which the brisk demand for til has had on the area. It seems, like linseed, to be encroaching on the area which has hitherto been sown with cotton.

The greater part of the til crop is sown in August, though in the southern districts, some is sown in October, and grown as a cold-weather crop. Breaks in the rainfall of August are, therefore, essential for the success of the crop, as seed cannot be got into the ground during continuous rain. It was the absence of breaks in August that made the 1884-85 season so bad a one.

The weather during last August was, on the whole, propitious for til sowings, though it is reported that the rainfall was too heavy in Mandla and Seoni. But the abnormally long break which prevailed throughout September and till the end of the first week in October has done the crop a great deal of damage, and, though some of the district estimates are probably below the mark, the outturn cannot be expected to exceed 9 or 10 annas in the rupee, taking 12 annas to represent an average crop.

The table referred to in the second paragraph we have been obliged to omit; but the following figures will give all the necessary information on the subject:—

	Approx. Area Acres.	Percentage. Acres.	Estimate outturn. Annas.
Saugor ...	36,000	+ 5	5
Damoh ...	18,000	+ 45	6
Jubbulpore ...	40,000	+ 11	7
Mundla ...	15,000	+ 1	6
Seoni ...	15,000	+ 4	7
Nurgampore ...	11,000	+ 4	9
Hoshungabad ...	17,000	+ 15	8
Nimar ...	36,000	+ 3	9
Betul ...	22,000	— 1	7
Chindwara ...	18,000	+ 3	7
Wardha ...	20,000	+ 62	8
Nagpore ...	27,000	+ 23	9
Chanda ...	40	+ 10	10
Bhandara
Balaghat
Raipore ...	10	+ 45	12
Bilaspore ...	9	+ 86	7
Sambulpore

The first column of figures represents the area under til in 1884-85; the second, the percentage by which area now under exceeds (+) or falls short (—) of that of the previous year. The third column represents the outturn of the crop in annas per rupee, 12 annas being equal to an average crop.

MANUFACTURE OF MAHUA LIQUOR.

[Communicated.]

CURIOSITY prompted the "inquiry," from the result of which I have been able to glean the following facts and figures relative to the manufacture of an ardent spirit, which is more extensively consumed than any other spirituous liquor in India. I refer to the *Mahua* spirit which is manufactured from the flowers of the tree of that name, which is botanically known as *Bassia latifolia*, and has a wide distribution—including the Northern Circars and other parts of the Madras Presidency, Western Bengal, Central India, the North-Western Provinces and Oudh, and elsewhere. The tree is middling sized, with very numerous branches, the lower ones spreading horizontally. The flowers, which have a high economic value, are so plentiful that as much as 25 to 30 maunds may be obtained from a single tree in one season. They not only serve as an article of food for the wild tribes in the Central Provinces, and poorer classes in other localities, but afford the desideratum—inmate here as everywhere—for strong drink, which would almost appear to be a necessity for human existence. The flowers are eaten raw by the natives and have a sweet spirituous taste; but owing to their strong and peculiar smell, they are generally considered a nuisance by other than those who have acquired a taste for them by use. The mahua flowers have already attracted the attention of European spirit manufacturers, and, if I mistake not, figure in our export trade. Drury states that the spirit distilled from them, when carefully obtained, resembles good Irish whiskey in taste. But however this may be, I can safely say that the smell is most revolting, which, my informant asserts, can be overcome by admixture with aniseed.

With these preliminary remarks, I will proceed with my notes of a visit to an "outstill," situated on the western confines of the Burdwan District in Bengal. This establishment was on the roadside along the Grand Trunk route, and combined at once distillery and shop. The licensee made and sold his liquor at once and the same, and the supply was always produced as per demand. He obtained his right by open competition at the public sales of these concessions, and had to furnish an amount equal to two months' rent as a guarantee of his *bona fides*. Over and above this security he has to pay his monthly rent in advance; so that on the whole, the executive is well secured against all contingencies. The "permit" provides that the operations may be carried on only during the day, i.e., between sunrise and sunset, but vending may continue beyond this period up to 9 p.m. It also provides that no liquor shall be sold to soldiers; restricts all transactions to cash—no trucking; precludes any one person from purchasing more than one gallon or six quart bottles of liquor per diem; prevents gambling on the premises; and warns the licensee against encouraging bad characters. A sign-board is indispensable, and the privilege of manufacture and sale is non-transferable. Moreover the Abkarry authorities can have free access to the books and accounts at any time; the penalty for failure in respect to any one of all the above obligations is forfeiture of license and perhaps prosecution. On the other hand, the licensee may make as much liquor as he can sell, and has full liberty of action as regards the price and strength of his liquor. The only embargo placed upon him is that he cannot have more than *one still*, nor distil more than *ten* gallons of spirit at a time. This is not a hardship, for production takes place at the rate of a fresh relay, when necessary, every half-hour, if sufficient "ferment" be forthcoming. The *modus operandi* is simple:—A maund of mahua flowers thrown into 18 gallons of water and the mixture allowed to remain for four or five days according to the season of the year. This "ferment" is next passed into a large iron vessel, embedded in clay and fixed over a fire-place. The "worm" is a bamboo covered with coils of rope-fibre, and the "receiver" an earthenware vessel of half the capacity of the cauldron. These primitive appliances suit their rude purpose roughly well. The first operation generally occupies an hour, and takes about two annas worth of firewood, but all subsequent operations only require half this time, with a corresponding reduction in the item of fuel. The outcome from 18 gallons of "ferment" (derived from one maund of mahua flowers) is 10 gallons of spirit, comparatively weak, which is divided with an equal quantity of water and retailed at 2 pias per bottle to those classes of natives who have no caste objection to alcoholic indulgence. The maund of mahua flowers at present costs As. 14; but the price ranges from As. 10 to Rs. 2-8-0 per maund, according to circumstances. When the flowers are scarce or unprocurable, *goor* is substituted, totally or partially, in the proportion of 3 seers of *goor* to 4 seers of mahua flowers. *Goor* is the dry

unrefined country sugar obtained after boiling down the juice extracted from sugar-cane. It sells at from Rs. 1-8 to Rs. 3 per maund. I may mention that the ten gallons of liquor obtained from the receiver is not spirit in the usual acceptation of the term. The first three gallons of liquor distilled is only *proof spirit*, the subsequent seven gallons being of little value from an alcoholic stand-point. But it comes in for "mixing." The first product of the still mentioned, when sold without adulteration, fetches as much as 4 annas per bottle, or just as much as a gallon of the common liquor.

In conclusion, it is only necessary for me to add that the seeds of the *Bassia latifolia* yield a large quantity of oil by expression, which is used for burning in lamps as well as for adulterating ghee, which it somewhat resembles, being of a thick consistency. It is sometimes used for culinary purposes by the poorer classes. In the "Materia Medica" of the Hindoos, this oil is recommended to be applied to the head in cephalalgia. The same authority also says that the distilled spirit obtained from the flowers "is described by Susruta as heating, astrigent, tonic, and appetizing." The wood is hard, very strong, and as the tree grows to a height of 40 feet, may be utilised for a variety of purposes.

MAHUA FLOWER.

Miscellaneous Items.

THE fears of famine in China are disappearing, and the country is quiet. The Empress has publicly declared her intention to open out the country with roads and develop its mineral resources gradually. Reforms in the administration will be undertaken shortly on all sides. Formosa will have a separate Governor, and the island will be opened by roads, fortified, and its mines worked.

WE understand that the Nilgiri Brewery has obtained the Government contract for the supply of malt liquor to the British troops in Burmah, and that under this arrangement the Company will have to supply 4,500 hogshheads annually for the present. This Brewery now has agencies at Bangalore, Madras, Trichinopoly, Secunderabad, and Kamptee, and it is in contemplation to establish Breweries at Cadgoody, in Mysore territory, and at Kamptee, but whether this will eventually be carried into effect remains to be seen.

THE potato, cabbage, turnip, wheat, barley, oilseed, &c., crops are in full awing. New potatoes from Benares are now procurable in the market, although very dear—2 annas a seer. When they become cheap they are sold at 2 pice per seer. Onions and spices are also very dear. We hope to get new cabbages within a week. Oranges are very rare in the market.—A few showers of rain are very much required, and would do a great deal of good to the standing crops.—The tals and the Gauges are now full of wild ducks and geese. Indeed this is a capital season for shooting.—Fever and coughs are still raging in the city.—Thefts are of every-day occurrence.

AT the end of July last, Mr. L. R. Burrows, Collector of Nilgiri, wrote to the Board of Revenue, to ask if the concession sanctioned on 30th October 1883, on behalf of cinchona cultivation, could be held to apply to lands held under permanent puttas, issued under Standing Order No. 38. "The Board are aware that, until recently, permanent puttas are granted in the case of lands devoted to agricultural purposes, as well as lands occupied as building sites, and it will also be seen that in many cases large holdings have been permanently assessed at very low rates of assessment, to the detriment of the interests of Government. For this reason I think that it is unnecessary to extend the concession to lands held on permanent putta." The Board resolved that—"The concession, granted 30th October 1883, is only a temporary indulgence, which was conceded in consideration of the depressed state of planting interests, and although it does not extend to estates held under the waste land rules, the Board recommended that it be declared applicable to land held on permanent putta. Although the assessment of holdings under permanent putta was not revised at the recent settlement, and although some of those holdings are very lightly assessed, this is not necessarily the case with all, and revision at settlement would probably not have entailed enhancement of assessment in all cases." The Board's recommendation was accepted by Government.

Selections.

ENSILAGE EXPERIENCE.

AS I have frequent inquiries by letter and otherwise as to the success of ensilage feeding at the State Farm at Tewksbury, I thought perhaps your readers might be interested if I should give an account of our experiments, and what success we have met with in a practice of about four years in that direction. The first experiment was last season, when milk from the different lots of cows was tested at two different times, one lot being fed with good English hay, the other on ensilage. The ensilage-fed cows' milk analyzed quite one per cent more solids than the hay-fed, the same quantity of grain being fed in each case. The next experiment was to determine whether sweet ensilage could be obtained by a process of slow filling and not tramping, simply keeping the mass level. This experiment, so far as sweet ensilage was concerned, proved a failure. The silo contained 350 or more tons. The mass, after a few days, rose in temperature from between 80 and 90 degrees, when we first commenced to fill, to 140 degrees ten feet, and 150 degrees one foot below the surface. It remained at this temperature for nearly a month, when the mass gradually cooled down to about 90 degrees and there remained.

As we were nearly four weeks in filling, there being intervals of four or five days between some of the filling to allow the temperature to increase, we have concluded that bacteria were not created to be destroyed in that way. The ensilage obtained was as good as any I ever saw, but somewhat acid, and the microscope disclosed bacteria. I do not ascribe its goodness to going through this heating process, but to its having been allowed to get well along toward maturity before being cut in the field, the ears being well along in the milk. When corn is cut into inch pieces or less, so large an amount of mutilated surface is exposed to the atmosphere, that it makes the very best condition possible for the formation of ferment, and as ferment is caused by bacteria, and as they are not destroyed by any degree of temperature which would be likely to arise by process of slow filling, cut ensilage must be more or less acid according to the degree of maturity when taken from the field.

In an adjoining silo 250 tons of corn fodder was put in whole, in the same state of maturity that the cut was. This came out perfectly sweet and has kept so well that we are feeding it at the present time, August 10. This in my opinion, is the only way that sweet ensilage can be obtained, namely by putting in the product to be ensilaged without injury to the cells of the plant, cutting the crop up as it is fed from the silo. There was rather more waste at the ends in the uncut ensilage than from the cut. This waste can be prevented in the future by keeping the ends weighted at night during the process of filling and keeping those ends the highest during filling, as the ends do not fill as solid as the centre.

In changing from acid to sweet ensilage there was no perceptible change in amount or quality of milk, or in the avidity with which it was taken by the stock. Cut in foot lengths there was about four bushels per day of waste butts at two feeds, from a herd of forty cows. When cut fine the waste is all eaten. The capabilities of ensilage feeding over the old methods seem almost incredible. From fifteen acres of heavy corn and ten acres of light, which, if it had been properly matured might have been grown upon five acres, there were kept at the State farm seventy-five head of cattle from early in November to the middle of May. Since then about forty cows have been fed, and will continue to be fed until past the middle of August, with the addition of thirteen cents worth of grain, consisting of two quarts of cotton seed and four quarts shorts per day, and not a pound of hay or any other feed. A more healthy looking herd I never had to do with. To make sure that their looks were not deceiving as has been claimed by some that this good appearance might be upon the same basis as the flesh or blood of the beer drinker is produced, the stomach of every animal slaughtered has been examined, and in every case been found to be in a perfectly healthy state, and this after four seasons of feeding ensilage. The herd averaged full 3,100 quarts of milk last year per cow. Now after this long trial of ensilage feeding the conclusions arrived at are these: That it is capable of trebling the stock capacities of New England, and can be used to great advantage, either in dairying or beef production. For the latter, the stock have all the advantages of summer feeding, with grain, the year round. If any doubt this statement, I would like to have them visit the farm and judge for themselves whether these things be so. I have a field of corn now growing which is wonderful to look at, and which will undoubtedly produce thirty tons of fodder per acre early in September; there are nearly twelve acres of it. The corn can be put

in silo at your convenience, only do not let time enough elapse between the fillings to allow decay to take place on top, which will commence in four or five days, before another layer is put on. This is a very important fact to know, as it saves a great expense of extra help and team work, which has been thought essential to insure success. The corn can be put in whole or cut, with good results in either case. If a farmer can afford the power and help necessary to cut the corn at time of filling, perhaps it is as well to cut it up at that time, if having it acid is no objection, and I think it is not.

The advantages of putting corn in whole are these: It takes less time and help; less cost of machinery, which is a great item with those of small means; it enables the farmer to take the more leisure time of winter to cut the corn up as wanted. If the corn is put in all one way and kept straight, there is no trouble in taking it out by cutting in four or five foot lengths with an axe and then running it through a common hay cutter every part will then be eaten. This season, by way of experiment, I have twelve acres of southern white corn, 8 acres of marble-head mammoth, and fifteen acres of common field corn, all to be used for ensilage, but the field corn will be allowed to mature the grain before the stover is ensilaged, but still will have too much moisture in the stock to keep well in the mow. Good results have been reported of this last plan.

GEO. D. FORSTALL,

Farmer at State Farm, Tewksbury, Mass.

—New England Farmer.]

WHEAT AT ROTHAMSTEAD.

SIR J. B. LAWES has published his annual statement of the wheat crop on his experimental farm at Rothamstead, where agricultural observations have now been continuously made for 42 years. So far as the results at Rothamstead may be accepted as illustrative of the general harvest of the country, they afford little that is encouraging to those wheat-growers in India and elsewhere who have been for so long waiting in hopes of a livelier English market. The rainless months of July and August were exceptionally favourable for ripening the crop and for harvesting operations. Sir J. Lawes considers that in few instances has there been a more rapid and cheaper in gathering of the harvest. The crop itself, however, had suffered somewhat from the variable weather in June. Wheat, says Sir John, this peculiarity that it never wholly fails, but hardly ever realises perfection. Only twice in the course of 42 years has there been what may be called a first rate crop at Rothamstead. Wheat requires a steady and progressive increase of temperature during the whole period of its growth. But in June there were great fluctuations of heat and a fall, on one occasion, of as much as 20 degrees. The crop was, nevertheless, a fine one. The unmanured plot, on which wheat has been grown, without any manure, continuously for 42 years, yielded nearly 15 bushels per acre; the plot dressed with farm-yard manure gave the high ratio of 40½ bushels per acre; plots dressed with various artificial manures ranged between 31 and 36 bushels. The striking characteristic of the year was the large difference between the yield of the farm-yard-manure crops and those artificially manured, which averaged 7 bushels per acre. Applying these figures to the wheat average of England, we should get from 2½ millions of acres, after deducting 2½ bushels per acre for seed, a total of 8½ million quarters for consumption. The amount requisite for consumption in the current year will be 25,860,000 quarters. The home yield, accordingly, must be supplemented by something over 17 million quarters of imported wheat. Last year England imported 18 millions of quarters against the estimated requirements of 16,300,000 quarters. There must, therefore, be large stocks on hand, and the probability of any improvement in the market is as remote as ever. Meanwhile the present rate of exchange, taken in connection with ruling Indian prices, gives the Indian exporter as against the English farmer a bonus of over five shillings per quarter as compared with the state of things when silver was 8d. per oz. dearer! This is a calamitous result for English farmers, whose occupation, so far as wheat-growing is concerned, may be said to be gone. On the other hand, the fall in the prices of sheep in the North of England within the last two years has been something portentous for the stock owner. For some classes of sheep it has been as great as 45 per cent, and the mean fall on all sorts is over 40 per cent. On the whole, the prospects of the English farmer were never darker. Should he and the newly enfranchised agricultural labourer awake to the fact that the competition which has ruined their business is fostered by the rates of exchange ruling between England and the silver-using countries, we may expect the bi-metallic controversy to

enter upon a new and very decisive phase. Nothing, however, can be more certain than that England by her present currency arrangements, by enhancing gold and depreciating silver, offers a distinct premium to the silver using countries on their exports and an equally distinct discouragement to their imports—two results from which the English farmer and the English manufacturer are, in the nature of things, the first to suffer. At present the popular belief in England is that the only sufferers from the depreciation of silver are the Indian Government and its officials. The calamity is, accordingly, endured with the proverbial resignation that is felt for other people's misfortunes. Practical Englishmen will feel and act very differently when they learn, as they assuredly soon will, that the main brunt of the burthen is falling on themselves.—*Pioneer*.

HOW MUCH SEED TO THE ACRE.

IN some crops farmers have learned that over-seeding, by causing the plants to crowd each other, lessens the crop, and have adopted about uniform methods of seedling. Thus, in the corn crop of the west we plant three feet nine inches to four feet apart each way, calculating upon three to four stalks to the hill, experience having demonstrated that this distance and amount of seed will give the best results. With the small varieties of corn grown at the East closer planting is permissible, and with the larger varieties south still greater space must be given. But when we come to the wheat crop no such standard rate of seeding is established. Some contend that two pecks per acre is sufficient, others double this quantity, and others still sow all way from one to two bushels per acre; the larger number, however, using about five pecks. In planting corn each hill is put in such manner that if the seed is good it will grow. In wheat it is different, as ordinarily grown quite a percentage of the wheat fails to make healthy plants from the imperfect manner in which the seed bed is prepared. If the same care were taken to provide each seed with proper conditions for germination and growth as in corn, it is quite certain that a less amount of seed would give better results than are now obtained from the seeding of from one to two bushels per acre. The *Colorado Farmer*, of a recent date, has a letter from a farmer on this subject of the proper amount of seed wheat to the acre, which is referred to Prof. Blount, of the Colorado Agricultural College, for comment. The farmer says that of land in the same field and under the same treatment, and seeded at the rate of 60, 75 and 90 pounds of seed to the acre, that which received 90 pounds was the thinnest on the ground and every way the poorest crop. There was little apparent difference between that which received 60 and 75 pounds per acre. But in the centre of the field, where the 75 pounds per acre was used, there was a strip 100 rods long on which the drill made five rounds sowing but 37½ pounds per acre. The only test of this yield, in comparison with that seeded at the rate of 75 pounds per acre, was by counting the bundles made, 100 rods and back, with an automatic binder, and in weighing fifteen bundles of each. The number of bundles was the same, and the weight varied but fifteen ounces in the fifteen bundles in favor of the thinly sown grain. Prof. Blount, in commenting upon the above results, says:

"For years I have advocated thin sowing of wheat under nearly all circumstances and in nearly all soils. Thirty pounds is enough if it be sound and pure and sown at the proper time. Not only in 'highly cultivated,' but in all land will 30 pounds do better, yield more and make finer grain than 60, 90 or 120 pounds of the same seed in the same soil. This is specially true such seasons as this when hot suns follow damp nights and frequent showers. Thin sown wheat, oats, barley and rye always stool better and have fewer short stalks and heads at harvest. When crowded so they cannot carry out their natural habits of tillering, the whole crop is enfeebled and consequently the grain deteriorates.

"I know of many who have thoroughly tested thin seeding, an account of whose success I will write up as soon as threshing is done. On the college farm for seven years I have raised over 300 different kinds of wheat, at no time sowing more than 30 pounds per acre. With the exception of 1883, when the hail destroyed the crop, every pound sown has produced from one to three bushels. * * * The difference of opinion existing among farmers as to how much seed to sow per acre arises from various causes. Most men do not sow less than 90 pounds for fear of not 'getting a good stand.' Others sow the same quantities their fathers did, never once thinking of another way, while others contend the more seed the larger yield. On the other hand, a careful study of the wheat plant has convinced more than one farmer that seeds crowded too closely, like two

waves coming together destroy one another, and that the soil too densely shaded degrades the grain. It is a fact not often noticed or well known that when, two grains of almost any seed are placed side by side in the soil one will destroy the other, hence the small yield from thick seeding. Every farmer who persists in sowing 90 pounds, in my opinion, throws away a bushel of wheat to the acre. He throws away enough bread to feed his family the year round."

Waldo F. Brown, an Indiana farmer, and well known agricultural writer, in a letter to the *National Stockman*, says:

"I am satisfied from several years' experience that one bushel of small grained wheat like the Fultz, sown on a rich, well prepared soil, will give as large a crop as the land is capable of producing. I have grown an average of thirty bushels to the acre on a field sown with three pecks of seed, and am an advocate of thin seeding if the land is in the best condition."

Farmers who have wheat yet to sow this fall can easily test for themselves the value of thick or thin seeding by sowing strips through their fields with different amounts of seed, and carefully noting the result during the season of growth and at harvest.—*Farmers' Review*.

INDIAN AND CHINESE SILKS.

TO THE EDITOR OF THE "ENGLISHMAN."

SIR,—Your contemporary the *Pioneer* devoted two columns the other day to certain proceedings of the Agri-Horticultural Society of India. Speaking of silk your contemporary displays a confusion of mind that is simply appalling. One sentence seems to refer to tussar silk and the next to mulberry. The writer says:—"At present India sells little but cheap 'waste silk'; whereas from Shanghai alone the French last year bought 8,000 bales of reeled silk. What makes this inferiority of India to China the more dispiriting is the fact that the keen-witted Chinese are simply acting on advice given over and over again by Mr. J. Wardle." Now, were these 8,000 bales tussar silk or mulberry? The commercial term "waste silk" seems to be the key-note for our contemporary's humble opinion of the India silk industry. It is unfortunate that commercial terms often convey a wrong meaning to the uninitiated. I have never heard that Indian waste silks compare unfavourably with the waste silks of China; but here the writer is evidently comparing China reeled silks with Indian wastes. I have given very special attention to this subject, and I should be indebted to the *Pioneer* for an enumeration of the ending suggestions made by Mr. Wardle. If the Chinese have been able to take advantage of them while our Indian cultivators have not, I fear the Indian press must be held in a measure to blame, since I make bold to say that no such suggestions by Mr. Wardle have ever been given in the public papers. But the question is, do they relate to mulberry or tussar, and do they refer to cultivation and rearing or to reeling? I have seen Mr. Wardle's pamphlet on the "Wild Silks of India"—a useful and convenient compilation of all that has been written on the subject of Indian wild silks, but I was not aware of any definite proposals or suggestions made by Mr. Wardle, and shall be much indebted to the writer if he would publish them.

But to continue the quotation:—"It is needless to point out the advantage possessed by this country over Europe in the matter of climate. Both the food plant and the silk-worms develop and multiply at a rate impossible in more temperate climes." Again, I ask, does this refer to the tussar or to the mulberry silk? If to the former, it is needless to say that to talk of the superiority of India over Europe is absurd, since the tussar cannot live in any part of Europe. The passage must therefore be held to refer to the mulberry, and it is strangely belied by the present stagnation of the mulberry silk industry. Observe that, from the prosperity of a part of the Chinese tussar export trade, a comparison is made with the Indian mulberry, and the superiority of India is extolled. For tussar India most decidedly is superior to any other country; it is the home of that worm, the cultivation of which has only within modern times spread to China. But for mulberry silk India is most unquestionably inferior, and the remarks I have quoted are sheer nonsense. The mulberry worm no doubt can be reared in India, but it is so exotic, and so also is the plant it feeds upon. We have several indigenous mulberry trees in the hills, but all are inferior to the white mulberry of Europe, and on the plains of India the indigenous species are as much exotic as the European plant. Attempts to conquer the obstacles offered by the Indian climate have been conducted for over 100 years, but we are as near success to-day as we were 50 years ago. The future for India in the silk market lies in a development of her wild silks,—the tussar,

eri, and munga, and in working these. China deserves imitation. I have always understood, however, that the success of the Chinese tussar was almost solely due to the large operations of Mr. Lister, of Bradford. As for Mr. Wardle's share in the matter, it is not as yet known to the world.

HORTICULTURIST.

COCA AT THE SOURCE OF SUPPLY.

THE Government organisation of the United States has been utilized to ascertain where the best varieties of coca are found, the best mode of preparing it for transportation, and how it can be brought within reach of the American purchaser. Dr. Squibb has had access to the reports received, and has communicated with his own correspondents. He has received a bale of coca from Bolivia by way of the tributaries of the Amazon and Para, but it had been ill-packed and was badly damaged.

Messrs. V. Faifan & Co., of La Paz, Bolivia, is one of the best and largest houses dealing in the article at the centre of the coca trade of Bolivia. Peruvian coca is smaller, narrower, thinner, and more fragile than the Bolivian; and a small proportion of the leaves want the characteristic faint lines forming a narrow ellipse with sharp ends on the underside of the leaf. Peruvian coca is bright green when fresh, changing to a "duller, lighter, yellowish green"; Bolivian is a dull, deep, olive green on the upper side, much lighter beneath, and becomes yellowish brown or brown. The two varieties shade off into each other, and both are divided into wild and cultivated, the latter being most esteemed.

The tree is cultivated on hill-sides 3,000 to 6,000 feet above the sea-level, on terraces on the sides of deep narrow valleys. The seed is sown in August in beds or boxes, transplanted in June to the terraces about 3 feet apart. The soil must be rich and free from shade and weeds, and is rapidly exhausted. The shrub grows to the height of from 2 to 6 feet, but the largest do not yield the best leaves. The crop is gathered, leaf by leaf, by Indian women and children. The first gathering, called the March crop, commences in January, the Saint John crop begins in May (St. John's is Midsummer day). All Saints' crop is collected in October, and then the shrub is completely stripped of leaves. Great care is taken not to touch the top of the bush. The leaves are dried in thin layers on hot pavements exposed to the sun, four hours' exposure being generally sufficient. They should not be laid out till the stones are quite hot. They are then packed for transportation across the mountains, and must be kept cool and dry. They are rarely handled or transported in damp weather or during the rainy season, which lasts from January to April. The only safe way of transporting them is in soldered tin or zinc lined cases. Salaverry, the port of entry of Truxillo, is the principal place of export of the Peruvian drug, Arica of the Bolivian, Mollendo being now closed by the civil war in Peru.

The Peruvian Government records a production of over 15,000,000 lb. per annum, the Bolivian Government 7,500,000 lb. Of the latter quantity, Mr. Gibbs, the United States Minister at La Paz, says about 55 per cent is consumed in Bolivia, 15 per cent each in the Argentine Republic and Chili, and 10 per cent in Peru, while the remaining 5 per cent, or 375,000 lb., is exported to the United States and Europe. If Peru exports the same proportion, the quantity received by the United States and Europe would be about 1,125,000 lb. The market report in New York is that one manufacturer of cocaine in New York and another in Europe have secured the entire crop for the year, while a third has secured "the remainder." A million pounds would yield at least 2,500 lb. of cocaine, while a fourth of that quantity would probably overstock the world.

Hon. S. L. Phelps, United States Minister to Peru, located at Lima, states that coca plantation producing good coca is sold in packages of about 14 oz., at a price which—incl. bagging, tins, packing, and transport to the wharf—is equal to \$31.75 per Spanish quintal, or about 320 (14 4d.) per lb. on shipboard. Minister Gibbs states that the price in Bolivia varies from 20s. to 45s. per lb. The whites of these countries seldom use coca except as an infusion, and then the first water is thrown away as being too strong. The habitual use of coca is said to prevent toothache and preserve the teeth. There is no evidence that the enormous demand in Europe and America has caused the slightest increase in Peruvian and Bolivian prices. Dr. Squibb points out that a drachm vial of a 4-per cent solution will last the ordinary practitioner a long while, and he asserts that it is highly probable that every manufacturer in the United States is overstocked with alkaloid. With coca yielding 4 per cent of alkaloid, or 28 grains per lb., at a moderate price, cocaine could be sold at 15c. per grain,

and any one of the four manufacturers in the United States could supply the whole demand. The Medical Department of the Army offered to contract for 2,000 grains. The competing bids were 18c., 19c., 19½c., 20c., and 22c. per grain or thereabouts. In consequence Dr. Squibb reduced his price to 20c., less 10 per cent.—*Chemist and Druggist*.

HYDROCHLORATE OF COCAINE.

Dr. FREUD, of Vienna, published in August a research on the alkalioid, which stated that it caused local anæsthesia of the tongue. Dr. Koller argued that if it deadened the sensibility of the nerves of the tongue, it would have a similar effect on the nerves of the eye. After many experiments on animals, on himself and friends, and afterwards on patients, he published his discovery at the Heidelberg Ophthalmological Congress in September.

We will give a short account of the results that seem to have obtained in various departments:—

THE EYE.—One or two drops of a 4 per cent solution instilled into the eye cause at first a stinging sensation, lasting a few seconds. On repeating the application there is a sensation of cold, then comes a feeling of weight or tension and dryness. The eye protrudes somewhat. If the instillation is repeated, the pupil dilates. Five minutes after the first instillation the cornea can be handled quite roughly, cut, cauterised with silver nitrate, pitted by pressure, without causing the slightest pain or even sensation. There is simply no feeling. When deep incisions are made, as for iridectomy, pain has been observed by some though not by others. It is as yet doubtful how deeply the anæsthetic effect can be made to extend; it passes off at the surface in about twenty minutes, and, as it apparently takes time to reach the lower extremities shown by the dilatation of the pupil, it would seem that the application must be repeated to obtain the best effect. The eye remains dilated for some time, but vision is not interfered with, and the eye gradually returns to its normal state. We find reports of three cases where inflammation has occurred after the use of the drug among a very large number, in which it was not observed. One patient who had undergone two iridectomies under ether had the globe of the eye excised by Mr. Carmalt Jones, under the influence of a 2 per cent solution of cocaine. His remark was that it was a great deal better than that honestly ether.

EYELID.—Mr. Bader has crushed a tumour on the eyelid without causing pain to the patient.

THE TONGUE.—Mr. T. Smith applied a 20 per cent solution to the tongue of a patient three times within ten minutes. He then applied fuming nitric acid freely two or three times, so as to produce a definite burn. No pain was felt during the operation.

THE NOSE.—H. J. Butlin records his own experience. He has twice had the turbinated bones of his nose burned by Dr. Semon, at intervals of three weeks. The first operation caused intense pain and prostration. At the second the surfaces of the bones was painted thoroughly twice over with an interval of five minutes, with a twenty per cent solution of the hydrochlorate. "The effect was marvellous, far more so than I or even he, I think, expected. The burning was not felt by me more than the introduction of the brush in painting. I cannot say I did not feel the operation, but the sensation must be described as feeling, not pain."

THE LARYNX.—Dr. Semon has also removed growths from the larynx of a lady in whom, at the seven previous operations, the mere introduction of the instrument had caused alarming shocks. After painting the interior of larynx with the 20 per cent solution once, and waiting five minutes, he was able to introduce the instrument four times, and remove considerable portions of the growths, without the patient experiencing any pain at the moment, or a subsequent shock hypodermically.

Messrs. J. H. E. Brock and C. J. Arkle, of University College Hospital, have tried the effect of hypodermic injections. The effects which were common to all the injections were smarting, followed by numbness; redness round the point of injection; in from two to three minutes, sensation to touch was diminished, to pain and temperature completely abolished. In every experiment except the 4th, when half grain was injected into the forearm, the anæsthetic area was more extensive immediately above the point of injection than below. The extent of surface on which the above effects were produced was about half an inch above and a quarter of an inch below the point of injection; while for about half an inch around this area there was a slight diminution to tactile, painful, and thermal impression. They have performed two minor surgical operations painlessly after an injection of one-seventh of a grain.

We have given only some of the more striking pieces of evidence that have been brought forward.

Dr. A. Hughes Bennet makes a suggestive remark. He says that in an investigation undertaken in 1872, he demonstrated that the physiological properties of theine, caffeine, theobromine, guaranine, and cocaine, when administered hypodermically, were to all appearances the same. "Should it be proved that they have also similar effects when applied externally to the mucous membrane, it would be of importance from an economic point of view, as cocaine is extremely expensive, while the others are comparatively cheap."—*Chemist and Druggist*.

TRAPPING PIG.

"F.O.L." sends to the *Indian Forester* a recipe, and an apology for trapping wild pigs. It can easily be comprehended that in many districts pigs are an intolerable nuisance, and any method of getting rid of them all at once would be highly acceptable to the agriculturists:—

Cases are not rare where the disforestation of flourishing plantations has been considered necessary in order to deprive the black-coated gentry of their zenana-khannas and nurseries. They, too, often make themselves intolerable to the cultivators, and even a keen forest officer cannot help sympathising with poor Panjabi Sing or Jack Burman, who, driven to despair and wrath, fires the forest home of his black enemies. The poor chap is probably run in and punished, and the plague he tried to combat gets worse than ever, as a new and denser crop of grass springs up after the fire, which killed the trees, but did not destroy the grass roots. All the time, nothing is more easy than to catch every pig, in even a large forest; and this is how it is done.

Select a nice, quiet, retired spot to build your trap. The trap is built in the form of an oval, the longer diameter some 40 feet, the shorter some 30 feet in length. It is constructed of closely fitting palisades with the bark left on. They should be at least 2½ feet in the earth, 7 feet above ground, and sufficiently strong to stand the simultaneous charge of a score or more of pigs. The trap has two heavy sliding doors, exactly opposite each other. Experience has shown that this facilitates the catching immensely, as the old sows, which are the most suspicious, apparently feel safer between two open doors, and do not so frequently give the signal for a bolt. A side door on the same principle, ending in a funnel-shaped passage with another small outer door, serves to transfer the pigs into cages for transport. These sliding doors can be set in such a way that the pigs either catch themselves, which however is slow work, and only to be recommended when a few stray pigs are still to be caught, or the spring can be pulled off by a man, and the whole sounder may be trapped at once.

The pull-off is similarly constructed for either purpose. The wire and the rope end holding up the sliding doors must run over large well-oiled wheels. These rope ends terminate in a smooth iron ring, and the ring, when the doors are set for a catch, is hooked on to a smooth iron pin well driven home into a firm post, —low down if it is intended that pigs shall catch themselves; out of their reach, if a pull-off by a trapper is contemplated. A lever is placed between the ring and the post, in form of a long stick, in the pigs have to let down the doors: in shape of a shorter board with a wire through it, when the pull-off is to be done by a man.

The next thing is to build two *machans*, at a short distance of 30 to 40 yards from each side of the trap; to enable the trapper always to take up his position down wind. The trap is now complete, and the business of seducing the pigs to enter begins. This may sound doubtful, but nothing is easier in practice, and pigs may be collected in it from miles around.

Trains of coarse grain, more or less continuous, are laid from different parts of the forest, all ending near the trap, where shallow trenches are dug and are constantly re-filled with a small quantity of grain of sorts which should be covered by a layer of a few inches of soil, in order to prevent deer from entering together with the pigs. The former would soon make a *tabula rasa* of the food, and the animals would disappear before day-light. In less than a month the pigs become quite accustomed to the trap, and in a very short time to the trapper as well, who ought to be near the trap, or in one of the *machans* for another fortnight or so at the time of feeding.

Then comes the time for action. The trapper is early in his *machan* and pulls off when a sufficient number of pigs have entered the trap. Hereafter the trap can be set for self-action, to get hold of solitary boars and any other pigs that may have been left. The pigs should not be killed in the trap, or near it. The trapping must be done by the man to whom the pigs have grown accustomed, and any bungling in the catching should be avoided, or future takes will be rendered infinitely more difficult.

INDIA AS A WHEAT COMPETITOR.

THE *Pioneer Press*, St. Paul, Minn., publishes a four column letter addressed to it by Mr. J. L. Hauser, of Cawnpore, India, under date of July 17th, 1885. It treats exhaustively on the subject of wheat production in India, the methods employed, cost of production, and of export, etc., etc. As India has become our greatest wheat competitor in the markets of Europe, the subject is one of interest and importance to the American wheat grower. We therefore present, in condensed form, the substance of the most important points presented in the letter. The portion of India best adapted to wheat culture (but not the only wheat producing portion) is what is known as the north-west provinces, comprising an area about twice as large as the state of Illinois. The soil is alluvial in its character, very fine in texture, and composed of some kind of clay with a considerable admixture of sand. In its mechanical conditions it is very favorable to the farmer, whose implements are of the most primitive character. While as Mr. Hauser says, such a soil in Minnesota would be of little value and the soil of Minnesota, if it could be transferred to India would be sold for manure, the peculiarities of climate and meteorological condition are such as to enable it to store up a large amount of nitrogen from the atmosphere, supplying an abundance of plant food, and making it productive. In the preparation of the soil for a crop, the Indian farmer has a plough about as effective as the old-time narrow bull tongue of the south, to judge by the description, though ruder in construction, which simply roots up the surface instead of turning a furrow. It is drawn by a yoke of native bullocks from one-third to half the size and weight of our oxen. But the Indian farmer goes over his ground from ten to twenty times with this simple plough on ground intended for wheat, each working opening up the soil to the action of the sun, air and rain, and enabling it to store up plant food for the coming crop. He also is careful to save and use every particle of manure possible, his poverty preventing the purchase or use of commercial fertilizers. Besides the plough, the only other implement used in preparing the ground for wheat is a log of wood drawn over the field as a clod crusher. The seeding is done by hand at the last ploughing, the sower dibbling the wheat in the furrow behind the plough at the rate of about 150 lbs per acre. The wheat is sown in October or November and harvested in March or April. The most of it is irrigated and is weeded by hand. The reaping is done with a curved hand-sickle, similar to that used for the same purpose in early times in this country. A day's work is stated by Mr. Hauser to be one-twelfth of an acre. This, we think, must be altogether too low, for in the days of hand-reaping in this country, a half acre was regarded as a day's work. The grain is threshed by being tread by cattle upon a hard dirt floor, the treading having a double object, that of separating the grain and of breaking up the straw fine to fit it for feeding, every pound being utilized for this purpose. The grain is cleaned by throwing with a wooden scoop in the wind. An average crop is seventeen bushels per acre for irrigated land and ten bushels for dry. The cost of the farmer's out-fit and of raising a acre of wheat is given by Mr. Hauser as follows:

COST OF OUTFIT.

Pair of Bullocks	\$ 12-00
Plough	40
Yoke	15
Leveller	30
Weeder	6
Winnowing scoop	3
Sickle	6
Water-lifter	50
Total	\$ 13-50

COST OF RAISING AN ACRE OF WHEAT.

Rent, per acre	\$ 3-60
Cartage of manure	1-20
150 pounds seed	1-65
Ploughing twenty times	75
Sowing by hand	15
Watering three times	2-25
Reaping and carrying	80
Threshing	35
Winnowing	8
Total	\$ 10-62

If the land is not of best quality or is at a distance from the farmer's village, the rent is less than the above rate—in some cases not more than half. The total area in wheat in the North-west Provinces and Oudh is stated as follows:—Normal area, 4,965,633

acres; area in 1884, 5,186,338 acres and in 1885, 5,298,026 acres, or an increase of seven per cent over the previous year. Taking the whole of India, the total acreage in wheat for the last crop was 26,826,453 acres, producing 258,103,200 bushels, an average of between nine and ten bushels per acre for the entire country. The exports of wheat from India for the last six years are given in tons, which reduced to bushels gives the following figures:—

1879-80	3,659,233 Bushels.
1880-81	12,423,933 "
1881-82	32,106,866 "
1882-83	23,674,000 "
1883-84	34,928,566 "

Of the crop of 1884-85, there had been exported up to date of Mr. Hauser's letter, but about 25,000,000 bushels. But the total export, he says, may reach double this amount or 50,000,000 bushels. Heretofore the chief obstacle to wheat production and export in the interior provinces, has been the cost of inland carriage by bullock carts, the average cost off which was 1-12th of a cent per bushel per mile. The cost of carting wheat from Cawnpore to Calcutta, a distance of 694 miles was 57-8 cents per bushel, now by rail the cost of shipment over the same distance is reduced to 18-29 cent per bushel.

The Government of India is moving vigorously in opening up the country by the building of railways for the purpose of stimulating wheat production, and the effect is already seen in the increased acreage and still larger increased export; other and cheaper foods, such as rice and millet, taking the place in consumption of wheat, formerly consumed in the interior provinces, because the great cost of land carriage did not permit its export. The price of wheat at interior points of production for the second week in May 1885, as given by Mr. Hauser, ranged from 44 to 57 cents per bushel according to variety and distance from point of shipment.

A comparison of the cost of laying down wheat in Liverpool from Delhi, 890 miles from Calcutta, and Chicago 940 miles from New York, is given as follows:

Cost of wheat per bushel in Delhi	62½c.
Railway freight	20½
Ocean freight	20½
Total cost per bushel in Liverpool	\$ 1.03½
Cost of wheat per bushel in Chicago	1.02½
Railway freight to New York	19½
Ocean freight	7½
Total cost in Liverpool	\$ 1.29½

or a difference in favour of the Indian wheat of 16½c. per bushel, but it will be noticed that the price of wheat in Chicago, and of both railway and ocean freight are considerably above present rates and prices. At this writing No. 2 spring wheat is quoted at 82 7/8 cents, freight to New York 5 cents per bushel, and ocean freights down almost to ballast figures. Freight from Chicago to Liverpool are openly quoted at 21 cents per 100 lbs, or 12 3/5 cents per bushel on wheat, and contracts are made below these figures. Taking the present price of wheat 82½c. and rate of freight 12 3/5c., wheat can be laid down in Liverpool from Chicago for 95½c. But no one will claim that these figures furnish a remunerative price to the farmer who grows wheat, nor to the transportation lines which carry it to market. Living rates to both require not less than \$1.00 per bushel for wheat in Chicago, and 25c. per bushel freight between Chicago and Liverpool.

The wheat of India, while of several varieties, is classed under four general heads, viz., white and red, hard and soft. Irrigation which is common in India, is furnished by canals, tanks (artificial reservoirs), and wells, all of which are numerous. Where wells are used, the water is raised by bullocks working an endless chain with buckets, or in shallow wells, with the Persian wheel, with buckets on its outer circumference. The writer sums up his article as follows:—

In concluding this report, I will state what I think are the advantages and disadvantages of wheat raising in India: First—The wonderfully permanent productiveness of the climate and soil. Second, the use of irrigation, on account of which there can be no failure of the growth of a crop. Third—The facilities for inland transportation and cheap ocean freights. Fourth—The variety of seasons giving the farmer work in the fields every month in the year, thus making the wheat crop almost an extra or surplus one, the other crops supplying the labourers with food. Fifth—The cheapness of labor. All these combined indicate that the wheat-growing power of India will largely increase. The Government is planning in every way to increase the facilities of irrigation, introducing new seed, and improved methods of cultivation, and also urging that freights on wheat by the State and other railways be greatly reduced.

The drawbacks are: First—Heavy storms of wind and rain that cause the grain to lodge just before harvest, when it quickly spoils in the hot sun. Second—Heavy hail storms, and in some localities frost. The hail breaks the stalk or thrashes out the grain. Third—Rust, flies, and locusts or grasshoppers. All these, at times, greatly affect the crops, but they are accidents and expected to occur only occasionally.

The facts above presented, from a reliable source, are worthy of the careful consideration of the American wheat grower. The problem to be worked out by the logic of events, is whether he, with his labor saving implements but high cost of labor and of living, can maintain his supremacy in the wheat markets of the world against the Indian farmer with his rude implements but favourable soil and climate, but whose labor is worth but a few cents a day, and who has the Government actively engaged for his help in providing the means by which his crops can be cheaply transported to market. —*Farmers' Review*.

THE CORN CROP OF 1885.

Elsewhere in this issue will be found a special report upon the corn crop from our crop reporters in the states of Ohio, Indiana, Illinois, Iowa, Missouri, Kansas, Nebraska, Minnesota, Wisconsin, and Michigan. A careful compilation of the figures given in each State as percentages of acreage and condition, and a calculation from these of the percentage of yield or total crop as compared with that of 1884, gives the following results, which will be of interest and value to our readers:

Ohio—Acreage per cent, 129; condition, 120; crop per cent, 154.
 Indiana—Acreage, 105; condition, 115; crop per cent, 120.
 Illinois—Acreage, 112; condition, 114; crop per cent, 128½.
 Iowa—Acreage, 104; condition, 113; crop per cent, 117½.
 Missouri—Acreage, 101; condition, 96; crop per cent, 97.
 Kansas—Acreage, 114½; condition, 98; crop per cent, 112.
 Nebraska—Acreage, 109; condition, 103; crop per cent, 112½.
 Minnesota—Acreage, 104; condition, 86; crop per cent, 89½.
 Wisconsin—Acreage, 95½; condition, 85; crop per cent, 81½.
 Michigan—Acreage, 116; condition, 107; crop per cent, 124.

A comparison of the amount of crop in each of these States, with that of 1884, is shown by the following tabular statements, in which the figures of the department of agriculture were used for last year's crop:

	Crop of 1884.	Crop of 1885.
	Bushels.	Bushels.
Ohio	85,393,000	131,505,000
Indiana	104,757,000	125,705,000
Illinois	244,544,000	294,239,000
Iowa	252,600,000	296,805,000
Missouri	197,850,000	191,914,500
Kansas	188,500,000	188,720,000
Nebraska	122,100,000	137,362,000
Minnesota	23,630,000	21,148,800
Wisconsin	26,201,000	21,209,000
Michigan	26,022,000	30,185,000
Total	1,251,596,000	1,438,796,300
Excess over last year's crop	...	187,200,300

It will be seen that of the above States all show a considerable gain over last year, except Missouri, Minnesota, and Wisconsin, which fall short of last year's crop, the largest gains being in States where the wheat crops suffered most severely last winter, and where large areas seeded to wheat the previous fall were ploughed up and planted to corn. These ten States last year produced within a fraction of 70 per cent of the entire corn crop of the country, which the final figures of the department of agriculture placed at 1,795,000,000 bushels. Assuming that the country outside of these States will produce as much corn this year (and such reports as have come under our observation lead to the belief that this will be the case), we have then a total crop for this year of 1,982,000,000 bushels, the largest crop ever produced in this country; and all matured without injury from frost except in some localities where the production is so small, that the damage from this source has no appreciable effect upon the entire crop of the country. An increase in the eastern, middle and southern States of 18,000,000 bushels over last year's crop (quite likely to be realised) would bring the crop of this year up to the grand total of 2,000,000,000 bushels.—*Farmer's Review.*

TOBACCO CULTURE ON THE POOSA FARM.

Letter from H. CAINE, Esq., Assistant Manager, Poosa Tobacco Farms, Tirhoot, to the Superintendent of Andamans and Nicobar, dated 6th October 1885.

I have been requested by the Secretary of Revenue and Agricultural Department of India to send you full instructions as to the method employed here for cultivating, preparing soil, sowing, planting, and treatment while growing of tobacco. I shall endeavour to do so in as clear and concise a manner as possible, and hope you will have no difficulty in following out the instructions.

Preparation of Soil.—Tobacco land should be well drained up-land which has lain fallow some time, or that has had some light crop in it; this land should be well manured with well-rotted manure.

We plough our lands twice monthly. Just before the time for transplanting the soil is ploughed up and well pulverised by a benger or beam of wood drawn by bullocks over the upturned soil so as to bend it and to break up any lumps of earth.

The soil should be sufficiently dry for this purpose so as not to cake and harden.

Seed-Beds.—These should be made up in a suitable situation, that is, protected from the hot afternoon sun, having some building or grove of trees on the west side. The seed-beds should be raised some six inches off the ground, and have trenches dug all round so as to carry off any superfluous moisture; the beds should be well worked with a kodalie and good rotted manure well worked in. After pulverising the soil and levelling it, pick off any stones or other rubbish, and it will be ready for sowing the seed.

The size of the beds should be about 4 feet by 15 feet; this is more convenient than square beds as it enables the plants to be attended to without risk of destroying them by trampling on them.

Sowing the Seeds.—The seed is sown broadcast with the hand, mixed with some sand or ashes so as to sow evenly; care should be taken not to sow too thickly. About one chittack of seed

ought to be found sufficient for one of these beds which would furnish enough plants for one beegah of land.

After having sown, and if there is a hot sun, it would be advisable to cover the beds with light mats. The seed should germinate in 7 or 10 days at least. American seed does; Sumatra takes much longer.

The plants may require watering, which should be done with a watering-can with a rose, when the plants are well up and large. Only water seed-beds in the evening. As soon as the seedlings have leaves of the size of a penny, they are capable of bearing transplanting. Before taking up the seedling to transplant, water the beds well an hour beforehand; this is done to loosen the earth about the roots so that the plants may be taken up without injury.

To take up the seedlings they should be seized by the underside of the two largest leaves by the finger and thumb, having one leaf on each side, not by the stem, then pull up gently, taking care not to break the leaves. They may then be placed in an open basket. When the basket is full, it should be covered with a cloth if the sun is hot, and the seedlings slightly sprinkled with water and then carried off to transplant.

The seedlings are planted out in rows 3 feet by 2 feet apart, for which purpose a knotted cord is issued—the knots being 3 feet apart. This cord is drawn by two men—one at each end. Across the field or portion of the field at a distance of 2 feet from the outer edge, the cord is drawn out and then trampled upon by coolies. The knots leave an impression in the soil where the seedlings have to be planted. The cord is then raised and put down again at another distance of 2 feet from the first, and so on, till sufficient land has been marked off. This work can be done during the day, and the transplanting in the evening.

Transplanting.—Transplanting should be done in the evening if there is any sun; in cloudy weather, it can be done all the day long.

Rainy weather is most suitable as it dispenses with watering, and the plants settle better. A boy takes a basket of seedlings and walks up the row, dropping a plant here and there, where the marks have been made; he is followed by a man who makes a hole with a *kurpie* into which he places a seedling, and then presses the soil around the roots firmly with his fingers and then goes on with the rest.

As transplanting can hardly be done here without watering, a boy carrying a can without a rose follows the man who is transplanting, and waters each plant he comes across; but, as I mentioned above, if the transplanting could be done in rainy weather, the watering would be unnecessary. When growing the young plants require some attention.

After the plants have been planted about a week or so, weather permitting, it is advisable to loosen and open the soil around them with a *kurpie*, and also to eradicate weeds which may appear.

Later on, a kodalie may be used to work the earth between the rows.

As soon as the plants have made growth and begin to throw out flower or seed heads, which will take place in about eight weeks or so, they should be topped, viz., the flower heads should be broken off before they flower in this way.

The stem on which the head was found should be seized about two to three feet from the ground and snapped clean off by the hand or figures. This topping will cause the plant to throw out heavy leaves. The higher up the stem is broken off so will the leaves of the plant become thinner and smaller. We generally leave about ten or twelve leaves of each plant.

After topping, numerous suckers and offshoots will spring up; these should be promptly broken off as soon as they appear, as they take a lot of nourishment from the plant. The plant ripens in about three months. We cut here in January, and none but ripe plants should be cut.

How to cut ripe plants.—A tobacco plant is known to be ripe if the leaf cracks when taken between finger or thumb and pressed; and also when the leaves present a swollen appearance and have a heavy look. The stem when cut is full of sap, very thin rind on edge, the leaves are curved over, look mottled, the ribs of the plant get brittle and are easily broken off; when fully ripe, the plant is cut at one stroke close to the ground. The best instrument to cut the plant is with a *kurpie*. When cut, the plant is allowed to hang over on its one side and wilt or droop in the sun.

This wilting takes from one to two hours according to the strength of the sun. When sufficiently wilted (which is known when the plants look drooping and the ribs can be bent slightly without breaking), the plants are placed in a cart and taken off to the curing house. Plants should not be cut in rainy or cloudy weather, as it is obvious the sun would not be hot enough to wilt were the weather cloudy, and the rain washes off the gum, and thereby decreases the weight of the plant. Plants should not be cut after the rains unless the gum has returned to the leaves, which is known by their sticky gummy feeling. Trusting the above instructions would prove sufficient, I beg, &c.

(Signed) J. F. PRIOR,
Acting Secretary to Government.

HOLLOWAY'S OINTMENT.—Sores, wounds, ulcerations, and other diseases affecting the skin, are amendable by this cooling and healing unguent. It has called forth the loudest praise from persons who have suffered for years from bad legs, abscesses, and chronic ulcers, after every hope of cure has long passed away. None but those who have experienced the soothing effect of this Ointment can form an idea of the comfort it bestows, by restraining inflammation and allaying pain. Whenever this Ointment has been once used, it has established its own worth, and has again been eagerly sought for, as the easiest and safest remedy for all ulcerous complaints, in neuralgia, rheumatism, and gout, the same application, properly used, gives wonderful relief.

WHAT IS THIS DISEASE THAT IS COMING UPON US?

Like a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy and has evil forebodings. There is a giddiness, a sort of whirling sensation in the head when rising up suddenly. The bowels become constive; the skin is dry and hot at times; the blood becomes thick and stagnant; the whites of the eyes become tinged with yellow, the urine is scanty and high-coloured, depositing a sediment after standing. There is frequently a spitting up of the food, sometimes with a sour taste, and sometimes with a sweetish taste; this is frequently attended with palpitation of the heart; the vision becomes impaired with spots before the eyes; there is a feeling of great prostration and weakness. All of these symptoms are in turn present. It is thought that nearly one-third of our population has this disease in some of its varied forms. It has been found that medical men have mistaken the nature of this disease. Some have treated it for a liver complaint, others for kidney disease, etc. etc., but none of the various kinds of treatment have been attended with success, because the remedy should be such as to act harmoniously upon each one of the organs, and upon the stomach as well: for in Dyspepsia (for this is really what the disease is) all these organs partake of this disease, and require a remedy that will act upon all at the same time. Seigel's Curative Syrup acts like a charm in this class of complaints, giving almost immediate relief. The following letters from chemists of standing in the community where they live show in what estimation the article is held:—

John Archer, Harthill, near Sheffield:—I can confidently recommend it to all who may be suffering from liver or stomach complaints, having the testimony of my customers, who have derived great benefit from the Syrup and Pills. The sale is increasing wonderfully.

Geo. A. Webb, 141, York-street, Belfast:—I have sold a large quantity, and the parties have testified to its being what you represent it.

J. S. Metcalfe, 55, Highgate, Kendal:—I have always great pleasure in recommending the Curative Syrup, for I have never known a case in which it has not relieved or cured, and I have sold many grosses.

Robt. G. Gould, 17, High-street, Andover:—I have always taken a great interest in your medicines, and I have recommended them, as I have found numerous cases of cure from their use.

Thomas Chapman, West Auckland:—I find that the trade readily increases. I sell more of your medicines than any other kind.

N. Darroll, Clun, Salop:—All who buy it are pleased, and recommend it.

Jos. Balkwill, A.P.S., Kingsbridge:—The public seem to appreciate their great value.

A. Armistead, Market-street, Dalton-in-Furness:—It is needless for me to say that your valuable medicines have great sale in this district—greater than any other I know of, giving great satisfaction.

Robt. Laine, Melkham:—I can well recommend the Curative Syrup from having proved its efficacy for indigestion myself.

Fricksheim, Arbroath, Forfarshire, Sept. 23, 1882.

Dear Sir,—Last year I sent you a letter recommending Mother Seigel's Syrup. I have very much pleasure in still bearing testimony to the very satisfactory results of the famed Syrup and Pills. Most patent medicines die out with me, but Mother Seigel has had a steady sale ever since I commenced, and is still in a great demand as when I first began to sell the medicine. The cures which have come under my notice are chiefly those of liver complaint and general debility.

A certain minister in my neighbourhood says it is the only thing which has benefited him, and restored him to his normal condition of health after being unable to preach for a considerable length of time. I could mention also a great many other cases, but space would not allow. A near friend of mine, who is very much addicted to costiveness, or constipation, finds that Mother Seigel's Pills are the only pills which suit his complaint. All other pills cause a reaction which is very annoying. Mother Seigel's Pills do not leave a bad after-effect. I have much pleasure in commending again to suffering humanity Mother Seigel's medicines, which are no sham. If this letter is of any service, you can publish it.

Yours very truly,

(Signed) WILLIAM S. GLASS, Chemist.

A. J. WHITE, Esq.

15th August, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's syrup which he got from me has saved his life.

Yours truly,

Mr. WHITE,
(B)

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DENSITY, ATTENUATION OF BODY, ERUPTIONS, LASSITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the sequelae of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of *Wilkinson's Sarsaparilla*, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your Essence of RED JAMAICA SARSAPARILLA cured me of a Torpid Liver; all other remedies failed."—*Wart of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Datt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Cocoa, Cinnamon, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at the Office, Colombo, Ceylon, on or about the 1st of each Month, Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the T. A., as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Rs. 18), carriage prepaid.

As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

CALCUTTA :—SATURDAY, DECEMBER 5, 1885.

[No. 49.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 26TH NOVEMBER 1885.]

Madras.—General prospects fair ; continue favourable in Bellary and Anantapore.

Bombay.—River still low in Sind. Reaping of *karif* and sowing of *rabi* crops completed in some districts ; in progress in others. More rain wanted for *rabi* crops in parts of Poona, Ahmednugger, and Khandesh. Standing crops damaged by insects in two talukas of Panch Mehals. Cholera in parts of eight, fever and cattle-disease in parts of 13, and small-pox in parts of five districts.

Bengal.—No rain fell in any of the reporting districts except Chittagong, Dacca, and Khoolna. In Chittagong rain heavy and has done some harm to the standing crops. *Amun* harvest is progressing with prospect of a good outturn, except in the flooded tracts, and in parts of Behar which have suffered for want of October rain ; *rabi* crops generally look well, but want of rain somewhat interferes with *rabi* and poppy sowings. Price of rice has generally fallen. General health continues fair.

N.-W. P. and Oudh.—Weather seasonable. *Rabi* operations nearly completed everywhere, and crops so far progressing favourably, but want of moisture has affected the area sown. Prices steady. Health generally good ; cholera and fever abating ; condition of cattle fair.

Punjab.—No rain ; it is much needed. Slight fever in the Delhi and Peshawar districts, in the Kahuta and Attock tahsils of the Rawul Pindie district, and in the Dera Ismail Khan city ; cholera prevalent in a few villages of the Dera Ismail Khan district ; health elsewhere generally good ; rinderpest has appeared among cattle in the Shera tahsil of the Shahpore district. *Rabi* operations in progress. Prices rising in the Hissar, Umritsur, Lahore and Rawul Pindie districts, falling in the Mooltan district, and stationary elsewhere.

Central Provinces.—*Rabi* sowings have been nearly completed throughout the provinces, and as a rule are germinating well, although in some places the October rain was insufficient ; the cotton crop is coming into market and is fully up to anticipation.

British Burmah.—Slight cholera in seven districts, elsewhere public health good ; slight cattle-disease in four districts, elsewhere health of cattle good. Crop prospects good in all districts, except in parts of Hanthawaddy, Promé, and Moulmein districts, where more rain is required. Reaping of crops commenced in Hanthawaddy, Henzada, and Moulmein districts.

Assam.—Weather seasonable ; rainy in Cachar ; public health fair. *Kalajir* seems still to be lingering here and there in the Luki tahsil. Prospects of all crops good. Reaping of *sali* commenced. Common rice 16 seers 15 chittacks per rupee. *Matikalai* and mustard doing well ; *sali-dhan* being reaped.

Mysore and Coorg.—Crops in good condition, except at Tumkur where the late sown *rabi* needs rain. Cattle-disease in parts of Kolar, Shimoga, and Kadur. Prospects of season good. Public health good, except in the Tumkur and Shimoga districts, where fever is prevalent. Harvesting of *rabi* in progress, water and pasturage abundant. No material change in prices.

Beas and Hyderabad.—Weather clear and cool. *Kharif* being cut ; prospects of *rabi* good. Wheat 22 and *jowari* 26 seers per rupee in Amraoti. Cotton picking continues ; *abi* crops are ripe and ready for harvesting. Fever and *ague* prevail in some talukas, and cholera in Patlur taluka. Prices in Hyderabad—wheat 14, coarse rice 12½, white *juar* 20, *yellow juar* 27, and *bar* 15½ seers per current sicca rupee.

Central India States.—Weather seasonable. Prices stationary. Health and prospects good. Sowings of *rabi* approaching completion.

Rajpootana.—Weather cool and clear. Fever decreasing in Abu, Tanks and wells fair in all places except in Meywar, Kerowli and Dhulepore. *Rabi* sowings progressing ; fever to some extent still prevails in Marwar. Crops being gathered. *Jowar* being harvested in Marowti, where fever prevalent. Prices—wheat 22, barley 32, gram 32, *barja* 23, and *jowar* 30 seers per rupee. Stationary generally. Health good. Prospects fair.

Letters to the Editor.

TEA-BLIGHT.

TO THE EDITOR.

SIR,—In your issue of the 7th ultimo you stated that "the latest news from the tea districts is that blight is very prevalent in most gardens in the Terai." I therefore read carefully the succeeding issues of your much esteemed paper, for some remedy for Tea-Blight, which *A Quondam Tea-Planter* might have suggested. But as up to date he has not come forward with any suggestions, I presume to address you with the following method of removing blight from tea-plants which Mr. Kurz, some time Curator of the herbarium in the Royal Botanical Gardens, Calcutta, approved :—Plant *bhany* (*cannabis sativa*) between the rows of tea plants. This will act as a preventive to the attacks of *acar* and other wingless insects.

HEM CHUNDRA DUTTA.

Calcutta, December 1, 1885.

P.S.—I will reply to *Inquirer* shortly.

Editorial Notes.

We learn that a Royal Commission, consisting of Members of the Council of Agricultural Education, has been appointed at Melbourne to make enquiries as to the products, other than wheat, to the growth of which the climate and soil of that colony are adapted. Several specialists have been requested to send in papers on the subject.

* * *

In May or June last Sir J. B. Lawes read before the Royal Agricultural Society of England, a paper on "sugar as food for stock," in which his experience was unfavourable from an economical point of view to the use of sugar as a food for stock. A correspondent, signing himself E. Calino, has addressed a letter to the *Queenslander* (which will be found elsewhere), from which it would appear that it has been used most successfully in Queensland.

* * *

It is stated that the plant called *Ferula sumbul*, which grows in Russian Turkistan, has recently attracted the attention of medical science as a prophylactic against cholera on account of its exciting and antispasmodic properties. The juice of this plant is exceedingly bitter and has a musk flavour. The plant could not for a long time be conveyed to Europe because the natives of Turkistan were unwilling to show where it grew. Thanks, however, to the exertions of the famous *savant*, Fedchenko (now deceased), specimens were procured and have been acclimatized in the Moscow Botanical Garden.

* * *

AFTER reading all that has been published in the Bombay papers regarding oysters, it is a positive relief to turn to Mr. G. A. Sala's account of the Auckland natives. He says :

From personal experience I can vouch for the respectable dimensions, firm texture, and delicious taste of the Auckland

oysters, of which, for six pence, you may obtain sufficient to elevate to the seventh heaven of sybaritism an amateur of oysters, who, driven to despair at having to pay three shillings and sixpence a dozen for natives, had emigrated to the antipodes, not to invest in sheep or cattle runs, to dabble in grain, to speculate in land, or to gain experience—and lose money—in gold-mining, but to seek for molluscs plentiful, excellent, and cheap. The cray fish likewise swarm, and are as fine in flavour as they are at Trieste, which is saying much.

**

THE total value of the imports into British India during the six months from 1st April to 30th September 1885 amounted to Rs. 24,16,95,991, which shows a decrease of Rs. 1,21,12,702, as compared with the imports for the same period last year. The total value of exports during the same period of 1885 amounted to Rs. 37,41,00,261, as compared with Rs. 39,51,36,221, during the same period last year, showing a decrease of Rs. 2,10,35,957. These figures indicated plainly the great depression of trade. Taking the decrease in the value of exports and imports together, we have a falling off amounting to Rs. 3,31,58,659 during six months of the present year.

**

A HOME contemporary notices that the falling off in the consumption of coffee in England is attracting some attention. In 1860 the consumption, with a population of 29,000,000, was 35,671,381 lbs., or 1 23 lbs. per head. In 1884, with a population of 36,000,000, the consumption was only 33,016,256 lbs., or 0 91 lb per head, or a diminution of 25 per cent. On the other hand, the consumption of cocoa during the same period has increased from 0 12 lb. per head to 0 38 lb. per head. The increase in the consumption of tea shows an important increase. In 1860, 2 66 lbs. per head were consumed; in 1884 it was 4 82 lbs. per head. This decrease in the consumption of coffee is the more remarkable, since during the past few years a very large number of coffee houses have been established throughout Great Britain and Ireland. In some papers we see that the figures given are 69,000 tons in 1861, against 11,000 in 1884, a diminution of 28,000 tons since 1861, which is evidently an

**

ACCORDING to recent reports, the position of the jute industry in Germany is not very encouraging. The price of jute goods, we learn from *Kuklor's*, has seriously fallen. There has been a fall in the price of raw materials, but it is not at all proportional, while wages have suffered no reduction. One cause of the present unsatisfactory state of things is the lifelessness which characterises all markets, and the general falling off in consumption. The business report of the Jute Spinnerei and Weberei at Harburg strikingly reflects the general condition of this trade. These works had in operation at the close of the business year 8,700 spindles and 224 looms, and manufactured during the year 3,610,478 toll-lb. of yarn, 3,746,646 metres of material, 1,812,274 sacks.

**

IT is stated that at an experiment recently tried at the Inventions Exhibition Aquarium, by Mr. W. August Carter, with a view to discover how far fish are prone to sleep, it was found that amongst freshwater fishes the roach, dace, gudgeon, carp, perch, minnow, and catfish sleep periodically in common with terrestrial animals. The same instincts were found to actuate marine fish, of which the following were observed to be equally influenced by somnolence—*viz.*, the wrasse, conger eel, dory, dogfish, wrasse bass, and all species of flat fish. Mr. Carter states that, so far as he can discover, the goldfish, pike, and angler fish never sleep, but rest periodically. Desire for sleep amongst fish varies according to meteorological conditions. Fish do not necessarily select night time for repose.

**

FROM the recently-published agricultural statistics, it appears that New Zealand made great strides in wool exportation during 1884, when the quantity shipped amounted to 81,139,028 lbs., as compared with 68,149,430 lbs. in the previous year the largest quantity exported up to that time. Such a sudden

increase would lead to the suspicion that New Zealand shipowners had been killing the goose that lays the golden eggs; but, in spite of the great increase in the exports of mutton, which reached 12,703 tons in 1884, the stock of sheep also increased. The statistics show a great falling off in wheat exports, *viz.*, from 4,897,540 bushels in 1883, to 2,706,775 bushels in 1884. On the other hand, the export of oats increased from 1,619,784 bushels to 2,474,631 bushels, the latter quantity being the largest yet exported in any year.

**

THE imports of foreign live-stock and fresh meat from the United States and Canada into Great Britain has attracted considerable attention. The following statistics of the arrivals at Liverpool from American and Canadian ports during three months, from July to September last, will be read with interest:—July 9,989 cattle, 2,533 sheep, 33,280 quarters of beef and 3,116 carcasses of mutton; August, 10,946 cattle, 7,051 sheep, 32,112 quarters of beef, and 759 carcasses of mutton; September, 7,830 cattle, 2,918 sheep, 27,902 quarters of beef, and 1,130 carcasses of mutton—making the total imports for the quarter 28,765 cattle, 12,503 sheep, 93,300 quarters of beef, and 5,305 carcasses of mutton, whilst the preceding three months' shipments amounted to 26,190 cattle, 1,015 sheep, 115,285 quarters of beef, and 16,120 carcasses of mutton, thus showing an increase in the importation of cattle, sheep, and mutton, but a decrease in the consignments of fresh beef.

**

ONE of our exchanges notices that M. Houles, the French discoverer of the method of open-air or stack silo, reports the continued success of his method. The secret of the success of this method lies in such uniform and continued pressure as will secure the expulsion of the air and thus prevent decomposition. The material is carted to the place of stacking as fast as cut, without waiting for any drying, and is built up slowly and uniformly, allowing fermentation to start, making the forage more tender, care being taken to prevent the stock from leaning as it settles. When the stack is finished, the top is covered with inch boards projecting a few inches over the sides, and then weighted at the rate of about 2,000 lbs. to the square yard, with any convenient material, stones, earth, or firewood. The only drawback to the plan is said to be the difficulty in keeping the sides perpendicular.

**

IT is stated by a home contemporary that a staff of State agriculturists has been instituted in Belgium by royal decree, chiefly with the object of popularising the theory and practice of scientific agriculture. The members of this body are to put themselves in direct communication with the cultivators of the soil, giving advice gratuitously to all who ask for it. Besides fulfilling the functions of travelling agricultural advisers, they are to arrange annually, in at least five districts of each province, a complete course of instruction on one or other branch of agricultural science or practice, suitable to the locality in each case. Experimental fields for the practical instruction of cultivators have been provided in each region, to be placed under the direction of the State agriculturist. The Inspector of Agriculture is to be the chief of the new body of officials, and over him will be the Minister of Agriculture, Industry, and Public Works, who will make all necessary arrangements for carrying into effect the royal decree. Agricultural councils and societies are invited to assist in the establishment and maintenance of the experimental fields. At present, eleven State agriculturists have been appointed.

**

A NOVELTY in dairy appliances was exhibited at the Dairy show recently held in London in the Delaitouse, a centrifugal machine for separating water or buttermilk from butter, instead of squeezing with the hand or using the butter-worker. The machine is made on the principle of the cream separator, which it resembles in appearance. The butter, in a granular state, as it comes from the churn, is put into a canvas bag, which, in its turn, is placed in a perforated cylinder in the machine. The cylinder is made to revolve very rapidly,

when, by centrifugal force, it throws all the water to the circumference, where it drains away, leaving the butter dry; and fit to be made up at once. In small dairies this invention is scarcely likely to oust the much cheaper butter-worker, but no doubt it will be used in butter factories and other large establishments. It was exhibited by the Dairy Supply Company, of Museum-street, W. C.

.

IMPROVEMENT in agricultural methods, says the *Universal Engineer*, appears to be making steady progress in the German Empire. The cultivation of beetroot has led to the practice of deeper ploughing and better working of the soil in the districts where it is grown, greatly to the advantage of crops subsequently planted on the same land. But in recent years there has also been a widely-extended increase in the use of agricultural machinery. The results of the census taken in June, 1882, show that there were then in use throughout Germany 836 steam ploughs, 19,631 reaping and mowing machines, 371,057 steam and other threshing-machines, and 63,842 sowing-machines. These large numbers have since been greatly augmented, and are being added to every year.

.

A GERMAN paper says that under the name "Salzungen cigars," cigars have recently come into the market which are made in Thuringia, especially at Salzungen. The firm* of Eichhorn and Forster, of Salzungen, has for two years endeavoured to introduce tobacco cultivation in the neighbourhood of that town, and not without success. The leaves of the better West Indian and North American tobacco plants, the seed of which is sown in German earth, are of a quality which far surpasses that of the ordinary smoking and cut tobacco. Of course, these fine tobaccos require considerably more care than the ordinary kinds, and for that reason more has to be paid for them. The importance to the cigar industry of the production of better sorts will be acknowledged when it is remembered that manufacturers can buy direct. The modes both of cultivation and harvesting are very different to the usual modes. The leaves are generally cut from the plant, strung on a cord, and hung to dry. Here, however, the entire plant is gathered and dried, the result being a superior aroma and quality. The tax law forbids harvesting after this American system, but by the interposition of the Meiningen Government and the concessions of the tax authorities, that system is carried on at Salzungen. The quality of the Salzungen cigars is spoken of in the highest terms.

.

THE National Pear Conference, which was inaugurated under the auspices of the Royal Horticultural Society, on the lines of the Apple Conference of 1883, was opened at Cheshwick on Oct. 21, when over 6,000 plates of fruit were exhibited. These included some 500 different varieties—specimens of 220 of which were drawn from the gardens themselves—and represented contingents from 40 different counties; Ireland, Scotland, France, and the Channel Islands contributing their share. The pear crop was generally abundant and good, and thus a splendid opportunity was offered by the show for examining the numerous varieties. It may be mentioned that there was no competition, and that no prizes were awarded at this show, the objects being the dissemination of useful knowledge, on the varieties most suitable for cultivation, a comparison of relative merits, and the correction of the nomenclature. Every exhibitor was invited to accompany his contributions with available information respecting soil, stocks, exposure, &c. In the show the fruit was grouped according to the county in which it was grown. The exhibition presented an endless variety as regarded shape, size, and colour. Some specimens gloried in the most brilliant orange and red tints, while others showed an exterior in tints of a dirty-brown colour; some again—notably those from Jersey—were a pound or two in weight, while others were scarcely larger than a gooseberry; not a few charged the surrounding atmosphere with the most appetising of aromas.

A NEW method of manufacturing cheese has been invented in Switzerland by M. Reber, which consists in heating the milk to a temperature of 86 degs. to 88 degs. Fahr., for some twenty-five to thirty minutes, when the colouring material and rennet are added. When the curd is fit to break, it is broken and placed in luen cloths, and then in the moulds, which vary in size according to the quantity of curd that is dealt with. It is next pressed, but as it is yet somewhat soft, it is generally found best to place it in a bath for five or six minutes, the temperature of which is between 127 degs. and 131 degs. Fahr. The crust of the cheese becomes hardened, although the character of the interior changes very little, and in this way the preservation of the cheese is much more easy. It is next pressed for twenty hours, then steeped in brine for from three to six days. The brine is made in the proportion of nine pounds of water to two and-a-quarter pounds of salt; but care is necessary in the salting operation to see that the cheese has more or less salt, according to the exigencies of the case. The actual profit is said to be about 10 or 12 per cent, and considering that a quantity of whey is left in the cheese in the process of manufacture, M. Reber does not think it is at all a bad return. The average price of the cheese, which becomes more and more pungent with age, is a trifle over 6.7 per pound.

.

OUR German contemporary states that the Magdeburg Association for the protection of the sugar industry has issued an interesting circular, in which it is stated that returns representing 289 German sugar manufacturers give the following data. The average yield of beets is estimated at 142.82 centners per acre against 157.1 centners in the last campaign. The 289 manufacturers will use daily in this campaign 371,050 centners of beets against 545,381 centners estimated, or a decrease of 31.96 per cent, as compared with last year. As to quality 92 works report that it is better, 116 that it is worse, and 74 that it is equal to last year's. A correspondent at Magdeburg writes that in many places a greater decline in polarisation than was expected is announced, so that the beet harvest will be below the original estimates. At present this circumstance has little effect on the sugar market, though it is probable that any further decline of sugar prices will be arrested.—It may be added that another estimate of the beet yield, based upon returns from 307 works, gives it at 142½ centners per acre against 156½ centners, and the total quantity of beets to be manufactured at 367,387 centners daily against 511,554 centners. The quality has, however, so much declined that the falling off this year will be about 32 per cent.

.

THE last *Assam Gazette* notifies that an Agricultural Exhibition will be held at Habigunge on the 1st, 2nd, and 3rd January 1886. There will be four sections of exhibits. The first section will include live stock, such as bulls, cows, bullocks, and buffaloes, ponies, sheep, goats, and poultry. The second will include agricultural instruments, such as ploughs, sugarcane-mills, oil-mills, cotton-cleaning machines, and other implements of agricultural use. The third section will include agricultural produce, grain, pulse, and tubers, fibres, cotton, and wool, oil-seed, sugarcane, and molasses, dyes, tobacco, &c. The fourth section will include all kinds of arts and manufactures. The show is intended primarily for the sub-division of Habigunge, but exhibitors from other places can be awarded prizes. No charge will be made for the admission of live stock and articles intended for exhibition. Prizes to the value of Rs. 500 will be awarded at the conclusion of the show. All produce, implements, and live stock intended for show should be sent to the secretary before one clear day of the show. All live stock and articles intended for sale must have their prices attached to them. Every facility will be given to effect sales, and no percentage will exacted on such sale.

.

MR. VERBECK, who was deputed by the Government of Netherlands India to report on the origin and character of the volcanic outbreak in the Sunda Straits in August, 1873, calculates, in his report just published, that the amount of ejected

matter from Krakatoa must have been at least 18 cubic kilometres. This would be enough to make a respectable range of hills about a thousand feet higher than the surrounding plain, and stretching from Lahore to Delhi. The velocity of ejection was considerably greater than that of the heaviest rifled ordnance and the ejected material must have reached a height of thirty miles or six times the height of Mount Everest, the highest mountain in the world. The noise of the explosions was heard over one-fourteenth of the earth's surface; and a great atmospheric wave starting from Krakatoa, as its centre, spread itself round the world, describing the whole circumference in some thirty-six hours. The mass of floating pumice found after the outburst on the surface of the sea, has been drifting in the direction of America, and the learned author times it to arrive off Panama early in 1886.

.

In mulching newly-planted trees, or those set for some years, says the *American Agriculturist*, we not only prevent suffering for want of moisture during the dry weather in summer, but enable them to obtain those elements which they require for nourishment and growth. In selecting a material for mulch, one of a fibrous nature, or at least one that will not become compact and hard, after being beaten by some heavy rains, is always preferable to any other. The more plant food the material contains the better, and for this reason coarse litter from the stable or farmyard has no superior for this purpose. Meadow hay may be ranked next in value, then straw, corn stalks, bog hay from low lands, and thence downward in the scale to pine or basswood shavings and sawdust. Almost any material that will shade the surface of the soil and admit air and water will prove of great benefit to newly-planted trees, and frequently restore to health the old and feeble or those stunted in growth from lack of moisture at the roots, and those fertilizing elements that can only be absorbed and utilized when presented in a liquid or gaseous form. Even small stones may answer.

.

THE following is the report on the state of the season and prospects of the crops for the week ending 25th November 1885:— Good rain continues to be reported from parts of the Madras presidency. The prospects of the crops are generally fair. In Mysore the crops are in good condition, though more rain is wanted for the late *rugi* in Tumkur. The *rugi* harvest is in progress, and pasturage is abundant. In Coorg the season promises well. No rain has fallen in the Bombay presidency during the week under report. The *khari* harvest and *rabi* sowings have been completed in some districts. In parts of Poona, Ahmednuggur and Khandesh the *rabi* crops need more rain. In the Berars and Hyderabad the *khari* is being cut and the *rabi* promises well. In the Central India and Rajputana States the crops are in good condition, and the *khari* harvest and *rabi* sowings are in general progress. In the Central Provinces *rabi* sowings have been nearly completed and promises well, though the October rains were deficient in places. A good cotton crop is expected. Rain is much needed in some places in the Punjab. The *khari* harvest is nearly complete and *rabi* operations continue. Seasonable weather prevails in the North-Western Provinces and Oudh, and prospects are favourable. In Bengal the rainfall of the past week has been confined to the districts of Dacca, Khoulna and Chittagong, in the last-named of which it has done some damage to the crops. The *amun* harvest promises a good outturn, except in the flooded districts, and the *rabi* crops are coming up well. In Assam the reaping of the *sali* crop has commenced and prospects are favourable. In British Burmah the rice crop is being reaped. The public health continues generally fair. Prices are generally stationary, except in the Punjab where they are fluctuating, and in Coorg and Bengal where they are falling.

.

MR. JOSEPH STEVENSON, Honorary Secretary of the Agri-Horticultural Society of Madras, has addressed the following letter to *Forestry*, regarding the history of the Mahogany tree:—

By this mail I am sending you a copy of the *Proceedings of the Agri-Horticultural Society of Madras*, containing a letter of mine giving the history of the introduction of the mahogany tree to the

East Indies, which would, I think, be interesting to many of your readers. The grand growth of the tree here has lately attracted attention, and Government is at present, with the assistance of the Kew authorities and the Government of Jamaica, endeavouring to increase it largely.

There is another subject in which I am deeply interested, in which you can probably assist me. There are to the north and south of Madras thousands of acres of sand-dunes which, within the last five and twenty years, I and others have covered with thriving forests of *Casuarina auriculata*, Roxb. The tree in favourable parts of the sands grows to a noble size, and that very rapidly. I have many 40 to 60 inches in girth at 5 feet from the ground, and tapering up probably 90 or 100 feet as straight as and very like a larch planted in 1871. A few trees cut for poles, shed building, rails and such-like uses, but hundred of acres go down in a very immature state every year for firewood. The wood is very hard, of great density and specific gravity, and bears a great strain, but is so liable to warp, perhaps from ignorance of the proper method of seasoning it, that it is very little used for other purposes. I have seen the wood take a very high polish, and some good tables and other articles of furniture made of it. It appears to me absolutely sinful to waste the well grown trees for firewood, and it has occurred to me that there might be a market for them at home for paving blocks, even if the wood will not season to prevent warping. The logs could, I believe, be profitable to put on board-ship at from £1 to £2 per ton.

.

THE October report of the Statistician to the Department of Agriculture, Washington, states that the last winter was the most destructive for wheat since that of 1866. That of 1881 was not so bad, as the portion utterly destroyed or so nearly a total destruction that other crops were substituted for it, was much less then. The worst part of the breadth was so generally given up that the remainder will average quite as well as the crop of 1881, which made a yield of 10.2 bushels, the smallest ever reported. The present average is about 10.5. It would have been 9 on the area planted, and not much over 9.5 if as large a portion of the area sown had been counted as in 1881. The area harvested is not precisely determined, but will probably not much exceed 34,000,000 acres. The indications are essentially the same as those of last month, pointing to about three hundred and fifty millions, possibly a trifle more, the exact figures of the final record of estimates depending on the precise ascertainment of the area harvested, a point of greater difficulty to determine the present year than in almost any previous year. The area, product, and farm value of the crop, will be placed on record in the December issue, after the December return of prices. The final record, after the verification of areas and tests of results harmonized, will not probably differ materially from former indications, which have a range of only 12,000,000 bushels in the fluctuations of condition from June to October, or a third of 1 per cent. The winter wheat decline in April and May, from a loss of re-sown area, unfavorable weather, and a clearer realization of the extent of the real injury, was 56,000,000 bushels. The results of June and July were favorable, and in several States the outcome was considerably larger than was expected on the 1st of June, notably in Michigan and Texas, the outcome being at the rate of 20 bushels per acre in the former State, a larger yield than has been previously reported. The reports from the Middle States, of the results of thrashing, show in many cases a better product than the appearance of the grain indicated. There are fields reported in Maryland in which the yield was 45 to 50 bushels per acre, furnishing new evidence of the profit and safety of good cultivation and fertility well sustained in an unfavorable season.

.

THE same report publishes the following regarding the cotton crop:—

The high condition of cotton in June and July was not maintained in August and September. Severe storms and excessive rains have prevailed; rust has destroyed the foliage, and worms have injured the fruit worse than for several years. Another fall in the average of condition has occurred, from 87 on the 1st of September to 78. The average in October of the census

was 81, and the ultimate yield four tenths of a bale. This year the greatest decline is in the region of highest rate of yield, reducing the relative production. The Department estimate of increase of area since 1879 is 20 per cent.

The returns relate both to condition and to prospective yield per acre in hundredths of a bale. The figures must not be considered final, as the date of killing frost and the autumn weather may easily cause a variation of a quarter of a million bales. Condition by States is as follows: Virginia, 78; North Carolina, 77; South Carolina, 79; Georgia, 87; Florida, 88; Alabama, 81; Mississippi, 80; Louisiana, 77; Texas, 78; Arkansas, 70; Tennessee, 74.

The expected yields, with average future conditions, are: Virginia, 82 hundredths of a bale; North Carolina, 84; South Carolina, 85; Georgia, 85; Florida, 88; Alabama, 80; Mississippi, 81; Louisiana, 43; Texas, 38; Arkansas, 42; Tennessee, 35. Average, 36½ hundredths of a bale. It indicates a million bales more than the present crop, subject to future meteorological conditions.

* *

Writing on the subject of bone dust as a fertilizer for wheat, the *Farmer's Review* says that in order to test the value of commercial fertilizers for crops in the State of Indiana, the agricultural department of Purdue University has for some years been testing them on the experiment farm. But in order to test their value under different soil conditions, it has commenced giving out stated quantities to farmers to be used in different localities under similar conditions. Last year it gave out to six farmers, residing in as many different counties, 200 pounds each of bone dust, to be used on plots of wheat, at the rate of 100 pounds per half acre, the fertilized half acre to alternate with unfertilized plots of the same size to be grown under precisely the same conditions, excepting the use of bone dust. The results, as shown by the reports of the farmers, are published in the *Indiana Farmer*. The conclusions drawn from the result of these experiments, as well as those on the college farm, so far as it is proper to draw conclusions from the results of the season's experiments, are given by Professor Latta as follows: "1. A suitable commercial fertilizer may be, in some cases, a partial protection against severe winters. 2. The effect of a fertilizer will vary with the kind of soil and the degree of natural fertility. 3. The value of rich soils commercial fertilizers are of doubtful utility, from a financial standpoint. 4. Farmers should carefully test various fertilizers in order to determine what will give best returns. While it may be true that there are some commercial fertilizers which may be used with profit by the western farmer, it yet remains true that in the clover plant he has an agency for maintaining the fertility of the farm of more value than all the commercial fertilizers in the market combined."

* *

An efficient remedy for mildew on plants is worth having. A correspondent, writing to the *Quebec Chronicle*, says:—

In your article on the Chrysanthemum, you say, "the first traces of mildew should be destroyed with flowers of sulphur dusted over it." Why flowers of sulphur, when there is a remedy so far superior available? Sulphur in that form is unsightly, inconvenient to apply, and, being insoluble, very imperfect in its effects. Some time ago I directed attention in your columns to a very soluble sulphur compound, sulphide of potassium, which, when applied in solution, say half an ounce to the gallon, leaves no unsightly effects, is easily distributed over the plant by the syringe, spray disperser, or by immersion, and which, so far from being in any way injurious, actually benefits the plant, even when applied to its roots, killing fungus in the soil and driving out worms. The solution kills all fungoid growth with which it comes in contact, but it is not sufficient in some cases to syringe only, as I have met with some forms of mildew which throw off the solution as a duck's back repels water; in such cases, contact must be ensured by the sponge or other means. An efficient, cheap, and easily applied remedy cannot be too widely made known, if consideration be given to the infinite mischief done to the vine, cucumber, hop, pea, rose, hollyhock, chrysanthemum, &c. (the list is too long to be enumerated in full detail), by various forms of fungoid disease. I intend another year to try its effect on the pear, soon after the fruit is set, as some of the best varieties in my garden are rendered worthless by forms of

fungus peculiar to that fruit; for this and other purposes, it is desirable that a spray disperser on a large scale should be contrived. No one who has ever tried sulphide of potassium would ever again have recourse to flowers of sulphur. Mr. Coleman, of Eastnor Castle Gardens, writes:—"I have given the small bottle of sulphide of potassium a fair trial, and the excellent result it has produced is more than satisfactory—it is marvelous; a gardener of his eminence would not have contented himself to term so strong unless he had thoroughly proved its efficiency. Sulphide of potassium is equally fatal to low forms of animal and vegetable life in animals, as in plants; consequently is a specific for the diseases caused by them, I can testify, after an extended experience of more than thirty years, in the words of Mr. Coleman, to the excellent, and, indeed, marvellous cures effected by it, often when skilled physicians had failed in various forms of skin diseases, contused wounds, whitlows, &c., in mange in various animals, grease in horses, gapes in pigeons, poultry, &c. It is very rarely used by the medical profession; they do not try it because it is not considered an elegant preparation, and as it has an odour often associated with sewers, may be supposed in these days of sanitary medicine to be injurious to health."

* *

Itabon FLEM, Vice-Minister, K.O.M., of Victoria, gives the following instructions for making potash:—"The wood, bark, branches, and foliage are burnt in pits one foot or 1 foot in the ground; the incineration is continued until the pit is almost filled with ashes. Young twigs and leaves are usually much richer in potash than the stem wood, hence they should not be rejected. The ashes thus obtained are piled in tubs or casks on straw over a false bottom. Cold water, in moderate quantity, is poured over the ashes, and the first strong potash liquid is removed for evaporation. But iron vessels while the weaker fluid is used for the incineration of fresh ashes. While the evaporation proceeds, fresh portions of strong liquid are added until the concentrated boiling fluid assumes a rather thick consistency. At last, with mild heat and fluid constant stirring, the whole is evaporated to dryness. Fully dried mass represents crude potash, more or less pure, according to the nature of the wood employed. A fire heating in rough furnaces is needed to expel sulphur and carbides, water, and empyreumatic substances; also to decompose coloring principles. Thus pearl ash is obtained. Pure carbonate of potassium in crude potash varies from 10 to 80 per cent. Experiments, so far as they were instituted in the laboratory, have given the following approximate result with respect to the contents of potash in some of our most common trees:—"The wood of the casuarinas, or she oaks, as well as that of the black or silver wattle, are somewhat richer than the wood of the bottle brush, but far richer than the ordinary pine wood. The gum of the Victorian blue gum and the so-called swamp tree (*Allocasuarina verticillata*) yield about as much potash as European beech. The foliage of the blue gum proved particularly rich in this alkali, and as it is heavy and easily collected at the sawmills, it might be turned there to auxiliary profitable account, and, indeed, in many other spots of the ranges. In the Queensland coast country the mangrove could be made to yield potash in immense quantities, as it is richer in this alkali than almost any other native tree or shrub, and even if the mangrove were not used for the manufacture of potash, the ash being rich in this valuable fertilizer, could be easily and economically applied for numerous purposes. Of course, British woodmen are aware that it is hopeless to compete with the extensive mineral deposits in Germany whence most of the potash of commerce is now made."

* *

The *European Mail* notices that some of the notes appended to the replies to questions relating to ensilage, collected by the Agricultural Department, are very suggestive, and others are astonishing. For instance, Mr. W. James, of Rodborough, Gloucestershire, states that twenty cows were the same time eating sixteen acres of hay as they were in consuming four acres of clover silage, although they had roots and cake with the light hay and none with the silage. Surely there must have been a very light crop of hay and a very heavy one of clover to give such a tremendous difference in feeding capability. The same witness remarks that sweet silage does not keep, on exposure, as well as sour silage. That is true, because

deterioration has done its worst in the case of the sour silage, and has not commenced previous to exposure in that of the sweet silage. Several witnesses remark that the chief advantage of ensilage is that it enables farmers to grow and preserve two green crops in the same season on the same land. One witness declares that the economy of ensilage is so great that, in spite of having a short root crop, he will be able to winter his usual numbers of 116 head of cattle and 1,200 sheep, and to sell 100 to 150 tons of hay as well. Experience has taught most ensilers the importance of keeping silage out of the cow-house at milking time, of requiring men who have handled silage to wash their hands before milking, and of removing the milk as quickly as possible from the cow-house. Such precautions against the tainting of milk are not necessary where sweet silage only is made. The following summary of the opinions of witnesses who have tested the effects of silage, upon the quantity and quality of milk and butter produced by cows fed on it, is as conclusive an evidence could well be in favour of the system of ensilage—

	Milk, Butter.	
No change	22	1
Improved in quantity and quality	95	15
Decreased quantity and deteriorated quality	1	—
Increased quantity	93	13
Decreased quantity	5	2
Improved quality	34	28
Deteriorated quality	5	3
Improved quality and decreased quantity	4	—
Increased quantity and deteriorated quality	5	—
Favourable results (whether in quantity or quality not stated)	30	15
Unfavourable result	—	1
Total number of opinions	294	79

The evidence does not warrant any general conclusions as to the quantities of silage most advantageous for stock of different kinds and ages, as practice varies exceedingly in this respect.

Forestry has published, from time to time, a series of interesting papers by the late Professor Walker Arnott, entitled "Historical notices of some celebrated trees." The last notice is of much interest, and runs as follows:—

Before concluding, I cannot refrain from drawing your attention to the *Dracena draco*, or dragon tree. I mentioned that the age of certain, but not of all plants, could be ascertained by means of the annual layers, and that the palm showed no layers. Now, although the *Dracena* is not a palm, it belongs equally with them to the great class of monocotyledonous plants, in which the deposit of woody matter is made in quite a different way from what we observe in the oaks, limes, cypresses, and others we have enumerated, all of which belong to the dicotyledonous tribe of vegetables. Now among those which have no annual rings the *Dracena* stands pre-eminent, and of these the famous dragon tree of the city of Orotava, in Teneriffe, furnishes a case of longevity perhaps transcending that of the oldest baobabs, or of the Mexican cypresses. This tree has been visited by many competent observers, and among others by that prince of scientific travellers, the veteran Humboldt, who has given a good figure of it as it appeared about 70 years ago, from a drawing made by M. Ozonne in 1776. A later and much fuller account was published in 1827 by M. Berthelot, and a fine figure of the mutilated trunk, as it appeared after the terrible storm of the 21st July 1819, forms one of the most striking pictorial illustrations of Webb and Berthelot's *Histoire Naturelle des Iles Canaries*.

The trunk is by no means equal in size to some of the dicotyledonous trees I have noticed. It is only 50 feet in girth at the base and not more than 60 or 70 in height. But, at the discovery of Teneriffe in 1492, over 4½ centuries ago, this dragon tree was nearly as large as at the present time, and had been immemorially an object of veneration among the natives. After the conquest, at the close of the fifteenth century, the trunk was employed as a boundary in dividing the lands, and as such is mentioned in ancient documents. It had changed very little since that period, until the summer of 1819, when a third of its spreading top was carried away by a tempest. But it still continues to vegetate, and its remaining branches are annually crowned, as they have been each returning autumn, perhaps for several thousands of years, with its

beautiful clusters of white, lily-like blossoms—emblems of "the eternal youth of nature." In regard to its real age, however, the usual means of investigation are defective, on account of the want of annual layers or rings; and apart from historic evidence, we can only form a somewhat conjectural estimate, by a comparison with young trees of the same species. M. Berthelot, who assiduously devoted many years to the study of the civil and natural history of the Canary Islands, and who has therefore attempted the comparison under the most favourable circumstances, declares that the calculations he has made, upon the supposition that the trunk has increased in size even at the rate of young dragon trees up to within the last 800 or 1,000 years, have more than once confounded his imagination. We cannot therefore but assign the very highest antiquity to such a tree, which the storms and casualties of four centuries have scarcely changed, and conclude that in the vegetable kingdom there are many living antiquities, compared with which the celebrated pyramids of Egypt are but the mushrooms of a single day's duration.

* * *

The agricultural returns of Great Britain for 1885, which were published on October 26, are summarized as follows:—

The area reported in 1885 to be under all kinds of crops, bare fallow and grass, exclusive of heath and mountain land and of woods and plantations amounts to 32,541,000 acres, as compared with 32,465,000 acres in the previous year, showing an increase of about 79,000 acres. The respective additions in each division are nearly 36,000 acres for England, under 9,000 acres for Wales, and about 34,000 acres for Scotland. Some small portion of the increase is doubtless due to the more accurate returns made by farmers, but the reports of the collectors state that the greater part is caused by the enclosure and reclamation of moor or heath and waste land in different parts of the country. With regard to the details of particular crops in Great Britain, the most noticeable features as regards corn crops, apart from the decrease in the total, seem to be that there is a considerable diminution of the area under wheat and an increase in that under barley and oats. The diminution of the area under wheat is almost unanimously stated by the collectors to have been caused by the low prices obtainable for this grain in the autumn and winter of 1884. They observe, likewise, that the tendency among farmers to devote more land year after year to breeding and grazing stock, as offering prospects of better results, has again greatly influenced the more limited acreage of this cereal in all districts where the nature of the soil and climate do not generally promise the probability of large crops, and the returns in the aggregate confirm the correctness of their statements. Turning to the various kinds of live stock in Great Britain, there is a noteworthy increase in cattle. Sheep and lambs show a proportionately smaller addition, but in pigs there is a considerable decrease. There is also a further decline of 14,000 in agricultural horses, accounted for in the same manner as was the reduction in the numbers of this class in 1884 compared with the previous year—namely, the diminished need of them owing to the smaller quantity of land under corn crops and the more general use of steam applied to agricultural cultivation, enabling farmers thus to economise labour. As regards horned cattle, the numbers exhibit an important increase in each of the several classes, the total number being now 6,597,964, or 328,623 (equal to 5·2 per cent) more than in 1884, and 635,165 (or 10·7 per cent) more than in 1883, the figures of the present year being the largest yet recorded for cattle in these returns. Sheep and lambs taken together show this year an increase of 466,000 over the numbers in 1884. There is a further decline of 181,000, or 7 per cent, in the number of pigs in Great Britain, the total being now 2,403,000. The number of poultry in Great Britain as returned in 1885, exclusive of those kept in towns or by cottagers with less than a quarter of an acre of land, is 15,963,000 as compared with 16,061,000 in 1884, a decrease of 98,000 on the total of the several kinds of poultry included in the returns. The returns of the crops and live stock in Ireland show a decrease in the cultivated area. The diminution extends to corn crops, green crops, and permanent pasture, while flax and rotation grasses each show a relatively large increase. The cultivated area shows the diminution in the past year of 23,800 acres, the area being now 15,219,000 acres compared with 15,242,800. As regards live stock in Ireland, horses have increased from 480,846 in 1884 to 491,147 in 1885. The several descriptions of cattle are also greater in number, the total being 4,228,751, or 2·8 per cent more than last year. Sheep and lambs have both increased, the number of sheep being now 2,138,299, and of lambs 1,339,542. Pigs, on the other hand, are fewer by 2·8 per cent, as there are

this year only 1,269,122 against 1,306,195 in 1884—a decrease of 37,073. The number of poultry has increased from 12,746,000 in 1884 to 13,849,000 in 1885.

POONA BOTANICAL GARDENS.

THE removal of the Botanical Gardens from Guneshkhind to Poona has formed the subject of some discussion between various Government officials who formed the Committee of Management. Before entering upon a review of the report, we cannot refrain from noticing the extraordinary delay which has occurred between the date of its submission by the Superintendent of the Gardens to the time of its receipt by us, which was only this week. The report itself is dated 25th May 1885; and the discussions which it underment ended on the 31st July last. We are indebted to the courtesy of the various Local Governments and Administrations for the supply of papers of agricultural interest, and value them much; but when, as in the present case, papers are received so long after their publication, they lose half their interest. However, to resume our review.

The removal of the Gardens from Guneshkhind to Poona was commenced in July, 1884. The Superintendent complains of the bad soil of the garden, and the unsatisfactory water-supply, which, notwithstanding that a canal runs through the grounds, is rendered practically useless owing to the level of the water being so very low. This defect will, however, soon be remedied, as a new water-lift has been ordered out from England. The want of plant houses is much felt, but a sum of Rs. 3,000 having been sanctioned for this purpose, the difficulty ought soon to be removed. Paragraphs 16 to 27 are devoted to descriptions of the various plots, and how they have been planted. The Carob tree, *Ceratonia siliqua*, is receiving attention at the hands of the Superintendent. Among fruits the litcher, guava, plantain, orange, lime, pomelo and grapes are mentioned as being under cultivation. Our personal recollections of the Narpore orange and plantain are, that there are few places in India where they can be surpassed. They ought to do well at Poona, where the climate is all that can be desired. With regard to the Mowilla hemp plant, the Superintendent remarks that he has 50; but that from previous experiments it is apparent that the difficulties in bringing to perfection the fibre are great, and that the cost of cultivation, &c., will not pay. He mentions the *Typha elephantina*. This is a plant of the bulrush order, and is said to form a good material for the manufacture of paper. The entire stock has been made over to a Parsee gentleman now in England, who is to have it tested there as to its paper-producing qualities. Arrowroot is also cultivated; but the Superintendent had not sufficient time for the experiment to say anything from personal experience; but he quotes the results obtained by Mr. Woodrow the previous year, which were that 200 square feet of land were cultivated, and the produce sold at the rate of Rs. 217 per acre. The weight obtained was at the rate of nearly 9 tons, 2 cwt. per acre.

The total expenditure during 1884-85 amounted to Rs. 11,811 as compared with Rs. 10,163 during the previous year. The total receipts during the same period amounted to Rs. 5,959, as compared with Rs. 4,916 in the previous year. The Superintendent complains of the paucity of his establishment, and asks for an increase. The conclusion we have come to after a perusal of the Superintendent's report is, that he is very considerably handicapped, both as regards the amount of funds at his disposal for expenditure, and the extent of his authority. That he is a practical horticulturist, we are fully convinced, but it seems that, if it is intended to turn this garden into a botanical repository, the idea of making it a self-supporting institution must be abandoned.

From the forwarding letter of the Collector of Poona, it would appear that the Government grant for the support of their garden is not sufficient. With reference to the question of a grant from local funds, either for the garden itself or the convenience of visitors, he thinks it would be inadmissible, and he would not recommend reliance being placed on the probability of obtaining private subscriptions. But that "if the

Government grant is insufficient the only way is apparently to increase it when possible." This is exactly our own view of the case; we quite agree in his opinion that, "whatever may prove necessary in the long run, there is no doubt that the more money that is spent now, under proper supervision, on labor, the sooner will the gardens be presentable and instructive; and he might have added 'the more economical will it prove in the end.'

Turning now to the discussions of the report by the members of the Committee, we find that much diversity of opinion was manifested as to the general character of the garden, and particularly as to the name it should bear. Mr. Ozanne, the Director of Agriculture, Bombay, expresses a very decided opinion against calling it a 'Botanical' garden, on the ground that the Superintendent's report is not encouraging, i. e. he "does not understand botany"; and that it is practically intended to provide a recreation ground for the soldiers and civil population. He therefore thinks the name 'Botanical Garden' would be anomalous. At the same time, if it is ultimately decided to convert it into a Botanical garden, he thinks that it would be desirable to have the active co-operation of Mr. Woodrow, the lecturer on Botany and Agriculture in the Poona College of Science, as his knowledge of botany would be invaluable in this connection. Dr. Cooke, the Principal of the College of Science, who is also a member of the Committee, agrees with Mr. Ozanne that the garden ought not to be called the "Botanical Gardens," as the title is misleading; but he deprecates the active co-operation of Mr. Woodrow in the work of the gardens, on the ground, firstly, of his not having the time to do so efficiently at his disposal, and secondly, for the reason that "it is very easy for a man in the position of the Superintendent of a Garden to ensure the failure of an experiment, even while seeming to be most earnest in its prosecution"; and goes on to say that he is quite certain that "if Mr. Woodrow were put in such a position as to be able to give orders to Mr. Shearer (the Superintendent,) the latter would, to use a common-place but expressive phrase, have 'his back up at once.'" This is exactly what would happen, and we entirely endorse Dr. Cooke's opinion. Divided responsibility has never been found to work satisfactorily, although, as Dr. Cooke says, it "has often been tried." We do not, however, think that the garden would be benefited by being placed under the Director of Agriculture, as that functionary already has as much as he can do to supervise efficiently the various agricultural and model farms in the Western Presidency, without having a hand in the direction and working of the Poona Botanical Gardens. Dr. Cooke's arguments that botany and horticulture are distinct studies, is only true in a limited sense. Some of the most successful horticulturists of the age are renowned botanists; take, for example, Messrs. W. Bull, B. S. Williams, James Veitch, and a host of others. Sir Joseph Paxton, one of the ablest horticulturists of his time, was a renowned botanist, as the works he has left bear ample testimony. The average run of "working" gardeners are certainly not botanists, nor do they lay any claim to a knowledge of the science; but a man got out to fill the post of Superintendent of a Botanical Garden in India under a covenant, must be strangely wanting in training if he does not possess a knowledge of botany. If he is not competent to name and classify plants, or to refer a plant to a natural order after an anatomical examination, he is unfit to hold the post of Superintendent, carrying such a high salary (Rs. 350 per mensem) as that drawn by Mr. Shearer. We cannot help thinking that Mr. Ozanne has taken a one-sided view of Mr. Shearer's qualifications; and if the latter were accused of being ignorant of botany, he would no doubt be quite indignant, and consider himself a much maligned man.

We ourselves fail to see why these gardens should not be called (and worked as) the Botanical Gardens. The Acting Collector, Mr. Eust, is perfectly right in what he says that, if properly named and classified, living plants in a garden are not less instructive from a botanical point of view than their dried remains in a herbarium; and that the "claims of both the Kew and Regent's Park Gardens to be called botanical gardens would scarcely be disputed; yet for one person that frequents them for scientific purposes, a thousand go for instruc-

tion of a more popular kind, and many more for mere amusement. The various Botanical Gardens scattered about India are not the less recreation grounds for their being called Botanical Gardens; and it seems quite absurd that the managing committee of the Poona Gardens should attach such importance to a name, even to the extent of abandoning or curtailing its sphere of action and usefulness. We might ask, in the words of the immortal William, "what is there in a name?" If we might be allowed to make a few suggestions, we would say that the best thing the Committee can do is to call the garden the "Botanical Gardens," and work it on the same principle as others of a similar character, and let the entire responsibility rest on the Superintendent. Mr. Woodrow may be allowed to advise Mr. Shearer where this becomes necessary, but no active interference should be permitted. Mr. Shearer should be answerable to some higher authority, say the Collector or Commissioner, for his share of the work. All construction should be carried out under the supervision of Mr. Shearer, as he will know best what is wanted, but the P. W. Department should do the work. Funds should not be started, as it is in the beginning that a definite plan of operations should be decided upon, for upon this much of the future success of the garden will depend.

Miscellaneous Items.

The assay value of gold and bullion received in the Indian mints from the beginning of April to the end of October was Rs. 66,42,859, and of those coined and examined Rs. 6,88,03,280. Of the latter amount, Rs. 2,41,67,203 was coined in Calcutta, and Rs. 4,46,36,077 in Bombay.

During the first seven months of the current year the value of gold imported to this country was Rs. 1,95,92,265, and of that exported Rs. 17,23,056; whilst the value of silver imported was Rs. 7,19,22,826, and of that exported Rs. 47,87,591. This leaves a balance of both metals in favour of imports of Rs. 8,50,01,141.

LOCUSTS are reported to have caused considerable damage to crops in the Vriddhachalam taluk of the South Arcot Collectorate. The remedy adopted to get rid of them was to light fires to windward in the case of winged insects, and to destroy the immature insects by driving them into trenches and thus destroying them.

It is said that when difficulty is experienced in keeping grass green under trees in open woods, particularly pine woods where the shade is continuous the year round, a little nitrate of soda sown occasionally throughout the growing season when the weather is moist will bring a fine crop of verdure pleasing to the eye and agreeable to cattle.

A NEW "everlasting" wood pavement has been brought out in France. The wood blocks are boiled in a solution of sulphate of zinc and chloride of sodium, mixed with a heavy mineral oil, linseed oil and tallow. The blocks are afterwards compressed to about one tenth their original volume. In this state they are said to practically defy wear and tear.

THE wood of *Allantus glandulosa*, a tree common in India, is, in the opinion of American lumbermen, much more valuable than it has been usually regarded by us in this country. Indeed, here the tree is grown almost exclusively for ornamental planting, and without any purpose of commercial interest entering into the calculations of the planter. It appears in America, however, to be regarded as one of the very best timbers for fencing, for that purpose being quite equal to locust wood and also about equal to oak as fuel.

THE Agricultural Durbar was to have been held at Lucknow on the 3rd instant, the day after the opening of the Exhibition, which the collected zemindars will thus have every opportunity of seeing. The Exhibition will also be visited by his Excellency the Viceroy during this stay at Lucknow, and on another day it will be given up to the zenanas of Lucknow, admission free. This plan of opening the sights to native ladies was a great success at Calcutta, and it is satisfactory to find it repeated at Lucknow. The Exhibition will probably close about the 12th December.

THE quantity of tea exported from China and Japan to Great Britain from the commencement of the season to the 10th of November last was lbs. 125,764,471, as compared with lbs. 124,932,260, during the corresponding period of last year. The exports to the United States and Canada during the same period amounted to lbs. 59,367,852, as compared with lbs. 57,887,325.

THE Hon'ble T. C. Hope left Bombay on Tuesday last for Bhopal, where he will meet Mr. Wilson Bell, the Agent and Chief Engineer of the New Indian Midland line, and Colonel Wallace, and in conjunction with them will arrange the plan of operations for the coming season. On leaving Bhopal, Mr. Hope proceeds to Umaria, to inspect the short span of line already constructed, which, when completed, is to open up the Umaria coal fields.

UNDER the title, *A Drop from the Indian Ocean*, Mr. Constable, who is so well known as an energetic member of the Lucknow Exhibition Committee, and who is singularly qualified to act as Mentor wherever industrial art and the higher flights of æstheticism are concerned, has published a most useful "Memorandum of Suggestions for the use of contributors to the Loan Collection Department of the Exhibition." These valuable "hints" are grouped under all the heads or classes into which the Exhibition is divided, and may be generalised as follows:—Products and Primary Manufactures, with their sub-divisions, minerals and ores, domestic pottery, metal-ware, &c. Arts and Industries, with their respective divisions: fine art, decorative musical instruments, jewellery, art-manufactures in metal, art manufactures in wood, ivory, &c., lapidaries' work, glass, textiles, embroidery, leathers and furs, articles of personal and domestic use, and a multifarious range of sub-divisions, the comprehensive character of which the official catalogue can alone do justice to. There are also suggestions relative to many special classes of exhibits.

SUGAR AS FOOD FOR STOCK

In the June *Sugar Cane*, page 297, we gave a paper by Sir J. B. Lawes, which was read before the Royal Agricultural Society of England, on this subject. Sir J. B. Lawes's experience was unfavourable, from an economical point of view, to the use of sugar for cattle feeding. The following letter, addressed to the *Queenslander*, shows that in that Colony it answers well:—

Sir,—I have read in your paper Sir John B. Lawes's experiment, "Sugar as Food for Stock," and as you in vite correspondence, I send this letter. Two years ago a two-year-old draught entire of mine, through neglect, got in such low condition that he could hardly stand. Grass was scarce and dry, and corn, even when well cooked, would pass through his body undigested; Besides, he did not care much about boiled corn, and he would not eat cracked corn, as he had a very bad lampas. The horse would drink milk, but as milk also was scarce I tried to make a substitute with sugar and flour dissolved in water. The horse took it, and I gave him five or six times a day one pint of sugar and one of flour dissolved in half a bucket of water. The result was wonderful. In a very few days he began to show a better coat, and to put on flesh, and having taken to boiled corn again—on which I put a sprinkle of sugar—his excrement showed that the corn was perfectly digested. So after a while I knocked off the sugar, and gave him the usual ration of corn and as much dry grass as he could get in the paddock. But very soon I had to return to the sugar, and I kept it up until some rain came to make the grass spring, for I could see the horse falling away and the food passing undigested. After again giving sugar the food was well digested, and the horse improved once more. A year ago I mowed some tussocky grass that was dry and white for several months before cutting. I built the haystack on top of a stable frame without tarpaulin or other covering over it. The hay was not good food then, and is certainly not improved since, and no stock will take a bite unless starved. By wetting this hay with diluted molasses or sugar it is preferred by the horse to good fresh lucerne hay, and if anything they are thriving better on it. The opinion that I have formed of sugar and molasses is this, and that although alone they are not able to sustain life, if fed in

conjunction with other food rich in azote they enable the stomach to assimilate the maximum of nutritive matter contained in such food. I believe that roots play the same rôle as sugar when fed in addition to grain, oilcake or other rich food. Every butcher must have noticed that pigs stop fattening when they have no more grass to root, no matter how abundant the animal food fed to them. When water and sugar is added to common milk for infants' use it is to render the same more assimilable, although the amount of nutriment is reduced. Upon runs that have been stocked a long time with sheep we often see in those heavily-grassed plains after a dry spell the sheep and cattle perishing; still the tussocky grass is there yet, and although whitened, the nourishment is there all the same, only the stock cannot digest it. It is then that sugar or molasses would be invaluable. I recollect reading in the *Queenslander*, a few years ago, that a squatter in New South Wales, after losing heavily, saved the remainder of his sheep from dying through bad feed by giving a very small ration of bran or pollard. I am convinced that a far more feasible plan, and quite as good in effect, would be to fence the dam or waterhole, and water the sheep or cattle, or horses in troughs, and add a small quantity of molasses to the water: this plan would also have the advantage of saving the weak beasts from getting bogged. As I have stated, my experiments on a large scale were confined to horses, but of all the animals that I have tried there was not one that did not prefer water sweetened to pure water. Sir John B. Lawes, in giving the result of his experiment that lentil and bran is to lentil and sugar as twenty-four is to thirty-one, remarks that the pigs left the bran and starch for the sugar, thus proving that not only is it more valuable, but more relished. If ever there was a time when molasses was necessary to save losses in stock it is now in the Maranoa district. The best station in Australia will shear only 30,000 instead of the 130,000,000 sheep shorn last year, and the cattle are dying in hundreds in every water-hole, notwithstanding that every man willing to swing an axe is engaged for cutting myall. Travelling is out of the question; they are too far gone, and there are no horses fit for the work, all the best horses having been sent to Yeulba and Dalby to recover, and the rest are kept alive with lucerne, corn and pumpkins; still the tussocky grass is not done yet, and the best plan would be to give them molasses in water. But let us inquire if it is practicable. We can have lucerne hay, the best, delivered in Roma for £7 per ton; maize and wheat, £10; but molasses, although only the refuse of agricultural produce, is charged £7 per ton from Brisbane for carriage alone; to this add casks and other expenses and you will see that although the most suitable for our distress, it is the dearest food of all—far more so than the best grain. Why not charge the same price for a full truck of 5 tons as is charged for refuse of building-down establishments? If it was carried at, say, £2 per ton to Roma, we would quite willingly give £3 per ton to the sugar-planter; and at £5 per ton delivered in Roma it would be profitable feed to use as a rule and invaluable at present as a medicine against worms. The most ludicrous aspect of the question is this: that most of the molasses made is thrown away every year as useless, because distilling does not pay. See these tables from Pugh's Almanac:—

			Molasses.	Rum.
			Gal.	Gal.
1875	438,950	made 343,244
1881	753,658	157,925
1884	1,071,413	144,073

Molasses increasing and rum decreasing! But this year the planter will not make low ration sugar, as it is unsaleable, so the amount of molasses not used will be enormous—and all lost! Considering the large increase in plantations since 1884, I consider that the molasses thrown away this year, if properly utilised, would produce more fat and flesh than all the maize and wheat produced in the colony, and so much wealth will be lost through excessive railway charges. A gentleman who is competent to express an opinion on the subject said to me the other day that half the squatters in the colony were insolvent, and the other half soon would be. I think the sugar planters are not much better, with their standing crop, scarcity of labour, and prices. Now one might help the other if only the matter could be arranged. I am convinced this is the only practicable way to save our stock from dying, for stock will take quicker to sugar than anything else—not excepting bran or corn.

I am, sir, &c.,
F. CALINO.

Mount Abundance, 4th August.—*Queenslander*.

THE INDIAN FOREST SURVEY.

THE following interesting paper was read before the Geographical section of the British Association, Aberdeen, on 11th September 1885, by Major F. Bailey, R.E., Superintendent, Forest Surveys, India:—

In his papers on the "Progress of Forestry in India," printed in the *Transactions of the Scottish Arboricultural Society* for 1884, Mr. Brandis, formerly Inspector General of Forests to the Government of India, writes as follows:—"The long period of peace, of good and just Government which followed the consolidation of the British Indian Empire, the construction of railways and other public works, and the rapid increase of trade and prosperity, have contributed much to accelerate the destruction of the forests of India. Over large tracts and entire provinces the forests have been cleared away to make way for the plough, and the increasing population, and when forests were left, most of the accessible timber was cut and brought away to be used as fuel and charcoal for shipbuilding, for railway sleepers, for bridges and other buildings. Hence it came to pass that forests, which in olden days were regarded as a thing to be got rid of, and as an obstacle to civilization, attracted attention, and that the necessity for preserving them began to be considered."

One of the first things to be done was to select and demarcate the principal forest tracts, so as to put a stop to further encroachments caused by the spread of cultivation, to free the demarcated area as far as possible from the rights which villagers and other persons possessed in them, and to frame a clear record of all rights which could not be so got rid of. The most important of the rights here referred to are the cutting of trees, tapping for resin, the collection of dead leaves from the ground, burning the grass, and the grazing of cattle, sheep, and goats. All of these, and many other such practices, are manifestly extremely hurtful to the forest, and unless they can be made to cease altogether, or at any rate unless they can be controlled and limited, forest conservation becomes impossible. But such rights are very difficult to deal with, for while on the one hand it is in the interest of the country at large that extensive and well-distributed areas should be permanently maintained under forest for the supply of timber and other produce to the population, the curtailment of them is frequently a matter of real hardship to the individuals who possess them. The fact that the continued exercise of injurious rights will ultimately destroy the forest, and thus render their further enjoyment impossible, is not recognized, and if this could be proved to the minds of the right holders they would not be much affected by it, as they are, generally speaking, satisfied if there is enough to provide for their own personal requirements without considering those of their descendants.

Although the Forest Act did not appear until 1878, the process of demarcation has been proceeding for the last thirty years, and the areas reserved on the 1st April 1883 were as follows:—

Bengal Presidency	...	35,667 square miles.
Madras	...	2,782 "
Bombay	...	9,823 "
Total	...	48,272 "

or about 5½ per cent of the total area of British India, not including the Native States. The forests now consist of the principal areas to which cultivation had not extended at the time that the Forest Department commenced its operations, and the chief of them had been saved from destruction, either because, in the absence of communications, they were inaccessible, or because they occupied ground which is too much broken to be suited for farming purposes, or which cannot be irrigated. The principal forests consist of extensive tracts of wild, almost uninhabited country, situated either in the plains or on the low ranges of hills rising from them, or on the lower and middle slopes of the Himalayas up to an elevation of 8,000 or 9,000 feet above sea-level. The want of protective measures in former years has resulted in the most serious deterioration of the forests which have now been reserved, and they, in many instances, include within their boundaries considerable areas which are partially or entirely denuded of trees, or from which the valuable species have disappeared. The ground, especially on the great hill ranges, is still, however, generally speaking, more or less densely covered with trees and jungle, and in the mountains many of the slopes and ridges are covered with a dense growth extending over large areas. The gradual deterioration and ultimate extinction of forests has gone on in all countries, and is still unfor-

unately in progress; but the necessity for preserving those which remain, and for reclothing denuded mountain ranges, is now recognised in most civilised countries. In France very large sums have been expended annually for the last twenty years in afforesting the slopes of the Forest Alps, the denudation of which has resulted in the most disastrous floods, and Colonel Playfair told us yesterday that the most stringent measures are being taken by the French in Tuile to arrest the process of destruction of the forests of that country before it has gone too far.

In Burma and in Southern and Central India, the principal trees are the teak and sandalwood; in the north-eastern portion of the peninsula the *sal* and the india-rubber tree are the most valuable species, while in the north-west the principal forests are stocked with *sal*, *sisoo*, and the *cutch* tree. These kinds are however, largely mixed with others, many of which are at the present time almost without value, and with *hambroos*. In the North-Western Himalayas the most valuable tree is the *deodar*, which is found mixed with several species of pines, *firs*, and *maples*, and also with *elm*, *hornbeam*, *birch*, and *poplar*.

Until the Forest Department undertook the management of these areas a few years ago, they were not thought to have any great value; it was supposed that they would supply the wants of the population in forest produce and grazing for ever, without the necessity for any special measures of protection, and nothing in the way of an accurate map of them was required. The system of management adopted by the Forest Department comprises not only protection against the illicit felling of trees and removal of produce, but also works of regeneration, such as planting and sowing, the making of export roads, inspection paths and timber slides, the cutting of climbers, protection against fire, and the sub-division of the forest into blocks and compartments with a view to arranging methodical plans of working. The damage done by fires in the Indian forests is enormous, and to control those which may break out, either within the boundary or on adjoining properties, a system of cleared lines is carried round and through the most valuable portions of forest, so that any block which becomes ignited may be isolated from the rest of the area. To enable a rational plan of working to be drawn up, so that the forest is secured against gradual extinction by the removal of more wood than can be replaced by the annual growth of the trees and by planting or sowing to replace those which are cut down, an enumeration of the trees, either over the whole forest or over representative areas of it, must be made. Such a "working-plan," or scheme of management, is essential for all forests. Trees cannot be dealt with like a crop of annuals which is sown and reaped in a single year; the age at which the most valuable timber trees are most profitably cut extends over several generations of men, and unless the principles of management are such as will conduce to the desired end, and unless continuity of aim and action can be maintained, failure is certain to follow. In order to guide and regulate the work of all kinds to be done in the forest, and to form the basis for a budget estimate, an annual plan of operations must be drawn out in which the work to be done in various localities is specified, and the lengths or areas are stated. The record of the rights of private persons or village communities within the forest must specify the parts of it in which each right can be exercised, while the roads or paths that may be used to lead cattle to certain springs of water, and the like information, must be clearly laid down. The boundaries and positions of all boundary marks must be recorded, so that further encroachments on the forest may be rendered impossible. Lastly, a careful record of all operations and of their results must be kept for future guidance. All this manifestly necessitates the provision of maps capable of showing a considerable amount of detail.

The Imperial Survey Department undertakes the preparation of maps on scales varying from 2 in. to 16 in. = 1 mile of lands which are assessed and which pay revenue, the rest of the country being surveyed by the Topographical Branch on the scale of 1 in. = 1 mile. Waste lands, or forests of comparatively small extent, lying enclosed within the assessed lands, are usually represented in the maps of the Revenue Survey Branch; but such lands are unassessed, either because they consist of broken ground, or because they are covered with dense jungle, or because they cannot be irrigated, and the accurate survey of such ground being both difficult and expensive the preparation of fully detailed maps of them was not, a few years ago, considered to be warranted by the good that could be made of them for revenue purposes; hence it follows that when such tracts were shown in the revenue maps, they were usually surveyed in less detail than the cultivated and revenue-paying country. But the most extensive and valuable forest tracts are situated within the area dealt with by the Topographical Branch, and thus it

follows that maps of them on a larger scale than 1 in. = 1 mile cannot be looked for from the Imperial Survey Department.

In the early days of forest management, maps on small scales and without much detail sufficed; but it is obvious that, to fulfil the numerous requirements which a more rational system involved, detailed maps on a large scale became an absolute necessity, and in 1872 measures were taken to provide them. It would have been inconvenient to the Surveyor-General's Department to be called upon to undertake the survey on an unusual scale of numerous comparatively small areas scattered throughout the country, while it was recognised that the maps were destined to meet special departmental requirements, and that there would be many advantages if their preparation were entrusted to a special branch of the Forest Department working under the control of the Surveyor-General. This arrangement was therefore ordered, and it has since worked most satisfactorily; the Superintendent of Forest Surveys has largely profited by the relationship in which he has been placed to the Surveyor-General, and at the same time the Government has secured a guarantee as to the quality of the work executed by him.

The scale on which the forest maps should be drawn formed the subject of much discussion, and in 1874 the officer who had been appointed Superintendent of Forest Surveys, happening to be on leave in England, was deputed by the Secretary of State to visit the Forest Survey Offices in France, Saxony, Bavaria, and Baden, in order to study the system adopted in the preparation of forest maps in those countries. On the one hand, it was essential that when the ground was gone over, the survey should be made on a sufficiently large scale to answer the special requirements on account of which it was undertaken, and that it should be executed on such a system and with such a degree of accuracy as would admit of its being made the basis of any further work that might subsequently be required; while on the other hand, as the cost of a survey increases at a high rate with an increase in the scale, it was necessary to adopt the smallest scale that could be made to answer the purpose. Ultimately it was decided that for the more valuable forests the scale should usually be 4 in. = 1 mile, while for those of less importance half the scale would suffice; and this has, generally speaking been found suitable, though larger scales have occasionally been adopted for small areas of exceptional value.

The scale determined, the superintendent had to raise and organize an establishment of surveyors and labourers, and he was fortunate enough at the outset to secure the services of Mr. W. H. Reynolds, an assistant Conservator of Forests in the Punjab, who has been for some years in the Imperial Survey Department, and also of three European surveyors, who had likewise been employed in the same Department. Aided by these gentlemen, and acting under the advice at all times so readily afforded him by the Surveyor-General (General Walker), he raised and trained a party of native surveyors, with whom he commenced to carry out the work before him. The first survey undertaken was that of the forests of Dehra Dun, in the North-Western Provinces. These forests, which cover an area of 573 square miles, are much interlaced with private lands, and as no good map of the latter then existed, it was thought desirable to construct a complete map of the entire district, the forests being surveyed by the new department, and the private lands by a party of the Imperial Survey. This joint work was not finally completed until 1876; but in 1875, when it was drawing to a close, the survey of the forests of Kumaun and Garhwal, also situated in the North-Western Provinces, and embracing an area of some 1,400 square miles, was commenced, and this has lately been completed. The survey of about 1,600 square miles of forest and private land in the Haiderabad Assigned Districts was commenced in 1881, and is now in progress. Altogether, since 1872, an area of about 8,000 square miles has been surveyed and mapped, nearly the whole of it on the scale of 4 inches = 1 mile.

Manifestly it will take a considerable number of years to work over the whole area, about 36,000 square miles, of reserve forests in the Bengal Presidency; but the preparation of detailed maps of the whole of these forests is not fortunately a matter of urgency at the present time, since for those which are in a backward condition, and in which nothing but simple protection can be undertaken for some years to come, any small-scale map with the boundaries marked on it, or a sketch-map, can be made to suffice for present necessities. A great deal of work has been accomplished by the Forest Survey Department, in the way of laying down boundaries on existing maps, and such maps have been found extremely useful, for it is very important that something of the sort should be placed

as soon as possible in the hands of the officers who are charged with the management of the forests.

When the survey party takes the field at the beginning of the cold season, the officer in charge finds himself in command of a small army of 25 to 30 surveyors, European and native, and perhaps 150 to 200 chainmen, flagmen, and others, for whose accommodation tents, clothes, food, and cooking apparatus have to be carried; then there are the instruments and tools required for the work, so that the amount of baggage is very considerable. To carry all this he has to hire camels or bullock-carts, and the whole party then marches by stages of from twelve to fifteen miles a day from its head quarters to the scene of the work, where the men are at once distributed over the ground. Each native surveyor is provided with the requisite number of chainmen and flagmen, as well as with the needful instruments and tools, and a definite piece of work is assigned to him. Four or five native surveyors are placed under the orders of one European surveyor, who is held responsible to the superintendent for the work done by them; it is his business to visit them constantly and check their work, himself giving the finishing touches to it, and he has a piece of independent work of his own in hand at the same time on which to occupy himself when he finds the opportunity. A camp computing office is established in some central position, and such computations as are needed at once are worked out as the field-books are sent in. The survey thus proceeds in the field for some six or eight months, and when, with the increasing heat, the forests begin to become unhealthy, or when sufficient work of this kind has been accomplished, the party moves back to head-quarters. Chainmen and flagmen are then discharged, or placed on half-pay, and the rest of the establishment is employed either in drawing maps or in computing the triangulation for the next season's work.

Considerable skill and experience are needed for the efficient control of such work, which, if not properly supervised and arranged, is sure to show this in inferior quality, insufficient quantity, or high rates. No hard-and-fast rules can be laid down for the execution of surveys; the officer in charge must vary the procedure according to circumstances, with reference to the nature of the ground and the requirements of each particular case in the way of amount and accuracy of detail. It is of course quite possible to produce accurate detailed maps of the most unpromising country, if time and money are of no importance; but as this is not usually the case, it has to be carefully considered how a map that will answer the required purpose can be produced in the shortest possible time and at the smallest possible cost, and all expensive processes, which are out of proportion to the rest of the work, must be studiously avoided.

The ground worked over by the Forest Survey Department often presents exceptional difficulties, of which some of the principal are the following. The ground is frequently very much broken and intricate; the crop of trees, fortunately for the country if not so from the surveyor's point of view, is often very dense, and where this is not the case, there is frequently a thick growth of bamboos or tall grass on the ground; it is very generally the case that good drinking water is obtainable only in certain places, at long distances apart; the forests are often infested with dangerous wild animals; and as a rule there is considerable difficulty in obtaining supplies of food, and great liability to attacks of jungle fever. The want of good water is frequently a cause of serious delay in the execution of the work, and, as the principal item of expenditure is formed by the wages of the men employed, it follows that slow progress means a high rate per acre. The surveyors must camp in the neighbourhood of a spring of good water, and if it is not near their work, they lose a great portion of each day in going out to and returning from the part of the forest in which they are employed—men climbing hills all day in a heavy jungle with a hot sun overhead are apt to drink a great deal of water, and if it be of bad quality, they are liable to be attacked by jungle fever or dysentery, and, in spite of all precautions that are taken to avoid it, a considerable number of the men are annually laid up with fever towards the end of the field season when the hot weather is coming on.

The wild animals which inhabit the Indian forest afford excellent sport for those who have the time to engage in it, which the surveyors have not, for the out-turn of good work of this sort is in direct proportion to the time spent on it, and arrears of surveying and mapping cannot be brought up by a stroke of genius; but to the unarmed native surveyor the presence of dangerous wild beasts in the forest in which he is called upon to work, affords no attraction, and cases have occurred in which they have caused the most serious inconvenience. On one occasion a native surveyor, having seen a wild elephant, decamped and could not be persuaded to re-enter that part of the forest, while his accounts of the terrors of the locality spread among the other men, and for a long time the ground could not be surveyed. On another occasion three native surveyors having seen a tiger, climbed a rock and remained there all night. In the morning they managed to convey an appeal to the officer in charge to come to their relief, which he did, but

without seeing anything of the tiger. This place was also in disfavour for some time afterwards. But a much worse case was that of the Jarhwal man-eater; this tiger had killed a very large number, some 300 or 400 it was said, of wood-cutters within the area which had to be surveyed. The superintendent was aware that if he lost one of his men, he would probably be obliged to abandon the work, and he took all means in his power to accomplish its destruction; but although the trail was twice followed, and the bodies of men who had been carried off were discovered, the tiger was not bagged. At last, as none of the survey party were touched, an idea gained ground among the men that the tiger bore them no ill-will, and they considered themselves perfectly safe, if they could satisfy him of their identity, which they were content to do by carrying aloft in a cleft bamboo, an old envelope from the superintendent's waste-paper basket!

The natives present a strange mixture of bravery and cowardice; they do not hesitate to express fear when they feel it, and do not seem to think that to be afraid is anything to be ashamed of, but at the same time they frequently perform acts that appear recklessly brave. An old man of seventy, armed with a tulwar, has been seen hunting about in the tall grass for a wounded tiger which was lying concealed close by him, and he had ultimately to be forced into a position of safety on the back of an elephant. On another occasion a bear had taken up his quarters in a dense part of the forest, and had killed several bamboo cutters, who had unwittingly invaded his retreat; a man who had just been mauled by him insisted on joining a passing Englishman, who went in search of the bear, and could not be persuaded to keep behind the rifle, but advanced boldly into the beast's lair, anxious to take a leading part in the retribution which shortly overtook him. The servant of a noted sportsman in the North-Western Provinces once proposed to his master that he should walk past a dense piece of cover in which a wounded tiger was lying, in order that the animal might be induced to spring out into the open, and thus afford a good shot!

Much may be done with such men, not only in the defence of our frontiers from foreign aggression, but also in more peaceable work such as that which is now treated of. The experience of the natives of India gained in the Forest Survey Department has been that, with skilful training and unimpaired management, almost anything may be done with them. From the very beginning they were taught that accuracy was of far more importance than rapidity of work or anything else; if a native surveyor thinks that his officer is not very particular, and would not be sorry to show a large outturn of work even at the sacrifice of something in the way of accuracy, he can develop the most astonishing powers of "fudging." To make certain that nothing of this sort should become the practice of the Forest Survey Department, a good deal of time was at first spent, not wasted, in encouraging the men to bring to notice discrepancies which occurred in their work, and in making them go over it again in order to bring it perfectly right, the officers being most careful never to be angry or impatient with them on account of any errors brought to notice in this manner. Thus a solid foundation for the execution of correct work was laid, and if progress was at first slow, and the cost of the survey was proportionately high, the men soon became more skilful, and the instances in which the ground had to be gone over a second time became fewer. In the beginning only, the more simple parts of the work were assigned to the native surveyors, and their drawings, which were not always very neatly executed, were incorporated in the field-sheet prepared by the European surveyor; but some of the best of them were not satisfied to execute work of this class only, and they qualified themselves by degrees to complete their field sheets almost entirely with their own hands, while a few of them can now sketch in the eye, contours with great accuracy, neatness, and artistic taste, always, as has been explained, under the careful and constant supervision of a European surveyor. The combination of Native and European labour in the Forest Survey Department has worked extremely well.

Detailed surveys of wild and densely-wooded country have rarely been made before in India, and in spite of the large proportion of the work which is done by cheap native agency, and the adoption of special methods of procedure to suit the exceptional nature of the undertaking, it is evident that such surveys as those described are likely to be more expensive than similar work in open, cultivated country. An additional cause for a comparatively high rate lies in the fact that the forest not infrequently consists of detached blocks, and this necessitates much moving about during the progress of the work. But the revenue derived from the Indian forests has largely expanded during the last few years, while the condition of the forests themselves has been greatly improved and their capital value enormously increased.

Good maps facilitate systematic and economical management, and enable work to be carried out and recorded in a manner which would be impossible without them; and to provide such maps, even at a somewhat high rate as compared with the cost of other maps on the same scale, is a necessity and a distinct economy.

LIMBURGER CHEESE.

MANY there are who have heard and read of it; numbers have smelled of and sniffed at it, and have sworn they would have no closer acquaintance; but they have returned to the charge, and from smelling have proceeded, to taste, and as in acquiring the taste for tobacco and opium, and of a few disagreeable things, have contracted a fondness for the article, and soon declared that it is the best cheese made. Others, and especially Germans and Hollanders, need not acquire the taste; a fondness for it seems to be a part of their make-up.

While the taste of this cheese when young is rich and creamy, and the flavor not particularly strong, its powerful odour when fully ripened has been likened to everything offensive, and the cheese, with its consumers, have by some become the theme of reviling and ridicule.

As its name indicates, Limburger had its origin in the province of Limburg, in Holland, where, with its peculiarity of shape, smell, process of making, and curing, it was formerly exclusively made. Thirty years ago its production in the United States was almost unknown, it being at that time thought, on account of the difference in climate and pasturage, impossible to produce it here. The same notion in regard to Swiss cheese prevailed, and consequently enormous quantities of both were imported from Europe to supply the large demand in this country. But it was found that both can and have been produced in this country in such perfection that the very best judges are unable to detect any difference from the imported article.

Thousands of tons of Limburger are now produced every season, mostly in the states of New York and Wisconsin, at a cost of less than half of the imported article. It finds its market and is consumed mostly in those cities containing a large proportion of Germans, Chicago, Milwaukee, St. Louis and New York. It is more profitable to the farmer and maker than any other kind of cheese; first, because from a given quantity of milk more weight is obtained, owing to the mode of making, and also because the price it brings is usually from ten to forty per cent higher than that obtained from the standard American cheese. In neighbourhoods where its manufacture has been commenced, it usually spreads to the exclusion of other kinds. Even the fastidious, shrewd Yankee, with his everlasting eye to the main chance, has found that the odour so execrable at first smells somehow of greenbacks.

In Green county, Wis., hundreds of tons are made annually, more than twenty factories being engaged in the manufacture. In Dodge and Jefferson counties large quantities are also made.

The cheese is made in factories capable of working the milk from 100 to 400 cows, rarely exceeding the latter number, as more would require a larger area of country than would be desirable on account of the factory, as the milk is hauled and the cheese made twice a day usually. The makers generally buy the milk from the farmer at a price agreed upon for the season of six months, beginning about May 1st. The process of manufacture in its first stage does not differ from the usual way, except that a lower temperature is kept while the curd is forming, the animal heat alone in summer being often high enough. Great care is taken to use pure milk, free from taint or fifth, and cleanliness is requisite in every stage of making. Upon the curd being formed, it is slowly and carefully cut into square pieces the size of dice, low temperature, and careful handling being necessary to avoid breaking the butter globules, upon which the richness of the cheese depends. It is slightly scalded and stirred, most of the whey drawn off, and without being salted, the curd is dipped out into perforated wooden boxes or mould, about five inches square, and left to drain without any pressure being applied. In a few hours the packages are carried into the curing cellar, and placed edgewise on shelves, like bricks set up to dry. Every day thereafter they are rolled in salt, and replaced when they have absorbed enough salt. They are turned almost every day, and the slimy moisture which exudes is rubbed with the hand evenly over the surface, which serves the double purpose of keeping the cheese moist and to close all cracks, into which flies might lay their eggs. This outside moisture decomposes while the cheese ripens, and being mostly composed of albumen, like fresh meat, eggs, etc., the same results follow the decomposition, and in this case the Limburger odour is developed, which never forsakes it, and sticks closer than a brother to all who touch or eat it. After eight or ten weeks it is packed in paper and tin foil, and is ready for market—in consistence, contents and nutriment the richest cheese that can be made, but, to the uninitiated, a malolious, predetermined outrage upon the organs of smell.—*California Patron.*

THE SILOS AND ENSILAGE RETURNS.

THE new 'Agricultural Department' of the Privy Council, as was noticed in our columns last week, have published a bulky and very interesting volume containing replies to a series of questions issued by the department to fully 1,200 owners of silos in Great Britain. Returns were received respecting 963 silos in England, 59 in Wales, and 161 in Scotland, representing nearly double the number of silos that were in operation in 1884 and the number is still being increased. While the majority of the silos appear to be on landowners' home farms, the practice of storing green fodder in this way seems to be making some way amongst tenant-farmers.

Where new buildings have to be constructed, farmers in backward times are naturally reluctant to incur the expense of silos, but in many instances old buildings, with some patching up, have been rendered suitable by an expenditure of only a few pounds. There was probably more than the lack of suitable buildings deterring agriculturists from extensive silo work. Many were doubtless, with characteristic caution, prevented from spending much money in that direction by a fear that the system would not prove a success. The first few years of its operations, however, convinced even the more sceptical that there was "something in the silo and in silage," hence the great increase in the number of silos as compared even with last year—nearly double.

The success of the system may be held as established, for among the 1,183 returns obtained, there are very few failures noted, and those that did occur, were traceable to mismanagement. Many details in the management are not yet sufficiently known to all who have

tried ensilage to enable mistakes to be avoided. Year by year, however, those errors may be expected to diminish. A comparison of the various experiences should be of great service to those operating with the silo, and that can be obtained from a perusal of the volume recently issued, which may be procured for the reasonable sum of twenty pence, exclusive of postage, through any bookseller.

It would have been noticed from what was published last week, that though the means by which the silage was made, differed somewhat, there is substantial unanimity as to the results. A few inches at the sides of the silos, as well as on the top, were unfit for food, but as a rule the rest was good, and was readily consumed by stock. Most animals did not relish it at the outset, but by-and-by took kindly to it. Young, growing cattle seem to have thriven best on silage. It kept them glossy in coat and in fair flesh, without turnips, and with a little cake, as well as straw or hay, and water. Fattening stock, it is believed, benefited by this new diet, materially aided, of course, as it was, by cake-meal, &c.; but its advantages are not so pronounced with fattening stock, as with growing animals and with dairy cows. It would seem that its value in the production of milk and butter is not quite so high as many were at one time led to believe. That is to say, it is not so much superior in the dairy to other and more common food for milk cows as has often been claimed for it.

It is difficult when cows are fed chiefly on silage, especially for some weeks after the diet has been commenced, to prevent a taint or 'taste' of the silage in the milk. That is about the only drawback to its extensive use among milk cows, and it is not so striking as it was. Those who supply comparatively small quantities daily to their cows, along with other foods, have not had much to complain of as regards taint of either milk or butter; but when silage wholly, or almost so, takes the place of roots, the milk does not so readily escape. Further experience, however, should enable owners of milk cows to modify the allowances of silage so that they would not predominate unpleasantly over the other stuffs in the dietary.

As to the safety of silage as food for cows heavy in calf, there are still doubts in some quarters, and consequently it has not been extensively given to animals in that condition. In-lamb ewes have been fed with it, and with no obviously bad consequences, while it is capital food for ewes after lambing and before grass comes sufficiently up. Given to young, growing cattle, the returns and remarks thereon show that silage has been a safe and a successful article of food—promoting growth and maintaining health.

The comparisons of the cost of haymaking with that of ensilage are interesting. Generally they are in favour of the former, when the season is dry and suitable; but how often is it that? There is doubtless more carting, packing, and weighting when the fodder is green than there is with hay thoroughly dried in the field or meadow; but then there is more hand labour at least with the hay, before it reaches the stack, than is required for the silage raw material, and there is the difficulty of getting it safely dried to be taken into account. One great advantage that the silo has, is that the forage can be put in in a wet state. No doubt it gives best results when it is deposited with no more moisture than the natural 'sap' of the plants newly out, but the results are wonderfully good where the grass and corn or vetches, as the case may be, are put into the silo in damp condition.

In moist climates, such as that of the west of Scotland and the north-west of England, where hay-making is often so tedious, and where there is so much grass land too, the advantages of the silo seem to be undoubted. Silos enable the storing of winter food for stock to be proceeded with in weather that it could not go on in under any other known process. That is no mean consideration. Some of the finest English-made natural hay would be ill to beat as an article of food for stock. Ensilage cannot surpass it, in our opinion; but, as some of the correspondents assert, first-class ensilage is better than second-class hay, and in wet seasons much of the hay is of a second or third rate character.

In a dry climate, such as that of East Lothian, there is less occasion for silos, especially when much of the hay is sold off the farm; but on strong land, in almost any part of the country, where root-growing is treacherous, the means of making ensilage might with advantage be within the reach of every farmer. Beans, peas, vetches, oats, and sown grasses, grow well on clay soils, while turnips are rather uncertain, and the former are the more suitable articles for the silo. Prikly comfrey has been introduced, but has not proved very satisfactory. Again, where, as in some parts of the west, there is a comparatively small acreage of turnips and a large portion under grass, the chief elements of successful and profitable ensilage present themselves.

Now that silos in Britain have got beyond the merely experimental stage, we hope to hear of a large increase in their number during the next few years. Not that we think ensilage is likely to supersede root culture, but it should lessen the area somewhat of that very expensive crop, and enable the farmer to tide his stock over critical periods more economically and better than he has hitherto been able to do.—*North British Agriculturist.*

HOLLOWAY'S OINTMENT AND PILLS.—Old Wounds, Sores and Ulcers.—Daily experience confirms the fact which has triumphed over opposition for thirty years—viz., that no means are known equal to Holloway's remedies for curing bad legs, sores, wounds, diseases of the skin, erysipelas, abscesses, burns, scalds, and in truth, all cases where the skin is broken. To cure these infirmities quickly is of primary importance, as the compulsory confinement indoors weakens the general health. The ready means of cure are found in Holloway's Ointment and Pills, which heal the sores and expel their cause. In the very worst cases the Ointment has succeeded in effecting a perfect cure, after every other means has failed of giving any relief. Desperate cases best display its virtues.

EXCHANGE AND THE INDIAN WHEAT TRADE.

THE *St. James's Gazette* of the 24th ultimo says:—We understand that one day last week a single house sold no fewer than thirteen cargoes of Indian wheat, shipped or about to be shipped, for delivery on arrival. We have in this an illustration of the extraordinary stimulus given to the export of wheat from India by the fall in silver. No doubt the effect of the fall has been heightened by the prospect of disturbances in the Balkan Peninsula; but the main cause of the large shipments is unquestionably the fall in silver. If a single house does so large a business in a single day, it will be understood how considerable must be the total business doing. No doubt so large an increase in the trade tends to raise exchanges, and it may be expected that, whatever Congress does with the Bland Act in its coming session, there will be a rise in the Indian exchanges by-and-by. If the Bland Act is not repealed the rise may be so great as to stop the export from India, unless there is a considerable rise in the price of wheat in Europe. Already there has been a rise in consequence of the events in the Balkan Peninsula. Should the prospect of a general war increase, the rise in wheat might be very considerable, and thus, in spite of an advance in the exchanges, the Indian exports might still continue to expand; but if the price of wheat does not rise, a rise in the exchange would undoubtedly check the exports; and should the Bland Act not be repealed, the rise in the exchange would be sufficient to reduce the exports to the scale of last year, probably.

The largeness of the exports of wheat from India render less probable that it seemed some time ago a rise in price. As the harvest was deficient both in the United States and in Russia, it was assumed, generally, that after Christmas there must be a considerable advance. It was known, of course, that the stocks of wheat all over the world are large, and it was assumed that the poverty of our farmers would compel them to hurry their corn to market as soon as they got it ready; but after a few months, the general impression was that there must be a considerable and sharp advance. The fall in silver, however, changed the situation completely. That fall has rendered it possible to export wheat with a profit from India, even at the present price. We are informed that shippers have a margin of about 2½ per cent, after paying all commissions and other charges. Should such a margin be maintained, it is the belief of those who are most competent to form an opinion that India can supply all wheat required by Western Europe. Much depends, however, upon the course of the silver market, and upon the weather in India. If the Bland Act should not be repealed it is, of course, probable that silver will rise considerably. Should it do so, it would hardly be possible, we presume, to continue those large shipments from India. Again, Indian wheat is being sown just now, and will be reaped early in the spring. It is believed that the heavy rains put the land in excellent condition, and the prospect is regarded, so far, as highly favourable at present. Should the weather throughout the winter prove equally favourable, it is estimated that the harvest next year will be even larger than any harvest hitherto; for, whatever may be the profits on shipping, it seems to be undoubted that the growers have received fairly remunerative prices, and that they will be tempted, therefore, to sow a larger area than ever. But, on the other hand, if the weather should prove very unfavourable, the harvest would be deficient, and then there must be either a considerable rise of price to tempt farmers to sell, or the exports would immediately fall off. Assuming, however, that the depreciation of silver continues, and that the weather in India is favourable, there seems every reason to conclude that India can go on selling at present prices all the wheat that we require.

THE DELAY IN THE DELIVERY OF INDIAN TEA.

We have recently inserted several letters from dealers in the London market, complaining of the great difficulty they have in obtaining delivery of tea when they buy it. It would appear that, on an average, about a week elapses between the day of sale and the furnishing of the weight notes to the buyer. Charges have been made by some of our correspondents of importers printing their tea for sale before the ship had actually entered the docks; but we trust that such occurrences are very infrequent, as we can scarcely believe that any respectable selling broker would habitually countenance so objectionable a course. It has not escaped our notice, however, that during the last week or two there have been several large invoices withdrawn from sale, and reprinted a few days later. No reason, of course, was assigned for the postponement, but it was quite understood by everybody in the market that the tea was not ready for sale when the catalogues were issued. We must express our conviction that the best interests of the Indian tea trade must suffer by such undue haste. It would seem as if everything must give way to crowding the tea into public sale directly it reaches this country. Hence arise complaints of careless bulking. Perhaps a break of fifty chests fine Broken Pekoe in an invoice may be ten short when the bulking operation commences, but the importer will not wait till the cargo is all discharged. The warehouse-keeper must bulk what he has got, and if the remaining ten chests are received a few days later, they can be bulked by themselves, or perhaps left as they are. How can such a system work other than mischief to the trade? And that it is of constant occurrence we have good reason to believe. Again, an importer is in great haste to sell an invoice of tea on a

certain day. He communicates his wishes to his brokers, who pass them on to the warehouse keeper. It may be a large consignment, and the time allowed quite too short. What then? The chests are opened and emptied out on the floor in heaps, and for days after, such heaps have been known to lie upon the warehouse floor exposed to all the pernicious influences of London fog and damp, before the warehouse-keepers' staff could find the time to fill the tea back into the chests. Of course, one or two chests had been filled, and put on show for the trade to draw samples from for the sale; but the remainder of the break was all the while absorbing damp. This is no secret to those who understand the way things are worked in the busy season; and we can well understand how, with such facts staring them in the face, dealers were ready to welcome the new system of bulking in India as a move in the right direction.

We should have been glad to have had a word from the opposite side. All our correspondents were plaintiffs, and put forward their charges in strong terms. There may be extenuating circumstances that have not yet been brought before the bar of public opinion, and having opened our columns for the free discussion of the whole matter, both as regards the delay in delivery question, as well as the size of the sampling breaks, or indeed any matter which affects the well-being of the Indian tea trade, we are still ready to insert any answer that can be made from the other side. We hope judgment will not be allowed to go against the importers by default.

We observe that the Committee of the London Wholesale Tea Dealers' Association are now taking the matter into consideration, probably with a view to the revision of the public sale conditions, and as there is certainly a grievance proved so far, it would be well if the matter were approached in a spirit of mutual good will, and with a desire to accommodate one another, rather than that the feeling of annoyance which prompted one of our correspondents to say that "life in the tea trade was not worth living," should any longer exist.—*Home and Colonial Mail.*

EXPERIENCE WITH CHICKENS.

The best egg-producing food I have found is a mixture of oatmeal and bran in the proportions of one-third oatmeal to two of bran mixed with boiling water, and fed in the morning only. It should be well mixed and not too moist, so dry you can squeeze no water from it, in fact in a crumbly condition. The oatmeal is fattening and stimulating, but inclined to be binding, while, on the other hand, the bran is light and easily digested, and counteracts the binding effects of the oatmeal.

The chickens should have exercise after eating. If fed at night, it is apt to sour in their crops, perhaps harden and make them crop bouni. But chickens need a change of diet, so I frequently substitute wheat middlings or corn meal for the oatmeal, but stick to the bran. At night I feed wheat cracked corn and buckwheat mixed. No screenings or refuse of the mills for my fowls. The best is good enough for them and the cheapest.

After feeding bran as above a few times, my egg product ran up from seven to twelve, fifteen, and even as many as twenty-five eggs a day from twenty-seven hens, in cold weather, when they were confined to their houses. My flock gets all the scraps from the table, and occasionally I buy a pound or so of meat, chopped fine and give it to them raw. They do not need this when they run at large and pick up worms and bugs.

Whole corn is good for a night fowl in winter, but is too heating for hot weather. They will eat whole oats, but if fed with wheat will eat the wheat first every time. It is well to alternate the ration of grains. Chickens like variety, and in their wild native state they get it.

The old fowls, or mature fowls, should have a small pinch of salt mixed with their morning food, as it will tend to keep them from plucking the feathers from each other and eating them. I think hens crave the saline taste at the end of the feathers. Salt in any quantity is fatal to little chicks. I have lost fifty this season in consequence of their having eaten food intended for the old ones.

Feed regularly, keep clean, treat kindly, and all ordinary fowls will reciprocate with a good yield of eggs. Keeping clean means they must have clean, well ventilated houses, and nests so sweet and clean that a hen will not feel it disagreeable to lay in them.

As to feeding young chickens, if they run with the mother they will require but little attention. Give them the bran and meal mixture three or four times a day, and small grain. Scatter plus-head oatmeal raw and where they can get it, but not as an exclusive diet. Bread soaked in warm milk, or even water, they are fond of. Some fanciers tell me that young chickens must have milk, but I have never seen an old hen give any, and as I have not any milk my chickens do not get any, and I have about 150 specimens from one week to two months old, and they are as healthy and lively as crickets.

I do not believe in the French plan of confining young fowls to one position and stuffing them by machinery in order to fatten them. This is unnatural and barbarous. An abundance of good food and proper care will make good broilers, and one only has to go to the flock and select what he wants in order to secure a delicious meal.

Cleanliness in the henery is rightly declared to be one of the chief essentials to success in keeping fowl. This is the season when fowls are most tormented with various kinds of vermin. Their houses should be fumigated with a brimstone smudge, then whitewashed, with a little sulphur or Persian powder blown into the feathers of the fowls will expel their enemies and save much unproductive labor.—*Ger., N. Y. Advertiser.*

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels costive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often-times there is a palpitation of the heart, and the patient fears he may have heart-disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARY-STREET, PETERBOROUGH.

November 29th, 1891.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

MR. A. J. WHITE.

WILLIAM BRENT.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer described it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Sd.) VINCENT A. WILLS,

Chemist-Dentist, Merthyr Tydvil.

To Mr. A. J. WHITE. Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

Preston, Sept. 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

To A. J. WHITE, Esq.

(Signed) W. BOWKER.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (having continued taking it), I am glad to say that I am a different being altogether. It is said of certain pens that they "come as a boon and a blessing to me," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CARRY B. BERRY,

A. J. WHITE, Esq.

Baptist Missionary.

Henningsham, Whitehaven, October 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(C.)

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA
SARSAPARILLAIS THE ONLY PREPARATION RECOGNIZED BY THE FACULTY AS A
WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DEBILITY, ATTENUATION OF BODY, ERUPTIONS, LASSITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*."We recommended your Red Jamaica Sarsaparilla."—*Medical Review*."The only preparation for removing what may be called the sequelae of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of Wilkinson's Sarsaparilla, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your Essence of RED JAMAICA SARSAPARILLA cured me of a Torpid Liver; all other remedies failed."—*Earl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Coca, Cinnamon, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at Observer Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the *T. A.*, as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Re. 18), carriage prepaid. As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

CALCUTTA :—SATURDAY, DECEMBER 12, 1885.

[No. 50]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 2ND DECEMBER.]

Madras.—General prospects fair; continue favourable in Bellary and Anantaporo.

Bombay.—River continues low in Sind. Reaping of *kharif* and sowing of *rabi* crops in progress in several districts. More rain wanted for *rabi* crops in two talukas of Poona, one of Nasik, and two of Khandesh, and in parts of Ahmednuggur. Standing crops suffering from drought in parts of Ahmednuggur, and from blight in parts of Bijaporo. Cholera and cattle-disease in parts of nine, fever in parts of sixteen, and small-pox in parts of five districts.

Bengal.—No rain during the week. Cold weather has fairly set in. Rain and wind of the previous week have done some damage to standing crops in East Bengal. *Amra* harvest is progressing, generally with prospect of a good outturn, except in flooded tracts. *Rabi* crops are coming up well, but in parts of Behar and Hazaribagh these crops and poppy are somewhat backward for want of rain. Public health continues generally fair. Rice cheaper than last year in almost all districts.

N. W. P. and Oudh.—Weather continues seasonable. Rain would be beneficial for *rabi* sowings where there is no irrigation. Prices are generally steady, and markets well supplied. Public health fair.

Central Provinces.—Prospects continue favourable. The *rabi* sowings are completed, except in the Chuttagurh division, and the harvesting of the *kharif* is in full swing. Weather unusually cold.

Assam.—Weather seasonable. Public health fair. *Kulaj* r seems still to be lingering here and there in the Luki tehsil. Prospects of all crops good. Reaping of *sali* crops progressing. Common rice 18 annas per rupee. Tea season is rapidly closing.

Mysore and Coorg.—Standing crops in good condition. Harvesting of *rabi* continues; Bengal gram, *jowari* and paddy being sown. Cattle disease reported in Kolar, Kadur and Shimoga districts. Prospects of season good. Public health good, except in the Tumkur and Shimoga districts, where fever and dysentery are prevalent. Water and pasturage abundant. Prices fluctuating.

Benar and Hyderabad.—Weather clear and cold. Jowar reaping and cotton gathering continues. Prospects of crops good. Wheat 22, *jowari* 26 annas per rupee in Amraoti. *Rabi* and *hi* crops prospering. Fever and ague in some talukas. Cholera abated in the Pathur taluka. Prices in Hyderabad—wheat 14½, coarse rice 12½, white *juar* 20½, yellow *juar* 27, and *tar* 15½ annas per current sea rupee.

Central India States.—Prospects good, weather seasonable. Health good, cholera still exists in Rewa city. *Rabi* and opium crops doing well. Opium sowing in progress in Manpore.

Rajpootana.—Weather clear and colder. Tanks and wells good in all places, except Sirahi, Pertabgarh, Meywar, Kerowli, and Dholepore, where they are drying. Fever still prevails in Marwar and Harowli. *Rabi* sowings in progress, completed in some parts. Crops average. Small-pox slightly prevalent in Meywar, where prices are rising. *Kharif* crops being gathered in Kotab. Prices steady. Outturn of *kharif* in Ulwar much below average.

Letters to the Editor.

RHEA GRASS.

TO THE EDITOR.

SIR,—In your issue of the 18th July last you published an article from the *Planters' Gazette* (English paper) regarding the cultivation of Rhea Grass. Will you kindly state how I can put myself in communication with "J. H. L." who contributed that article? Is the *Planters' Gazette* published in India, and if so, where?

ONE INTERESTED.

Pulicat, December 1, 1885.

NOTE.—The *Planters' Gazette* is published in London; and the best way for our correspondent to put himself in communication with "J. H. L." would be to address the Editor of that paper, who will no doubt do the needful.—ED., J. A.

FISH MANURE FOR TEA GARDENS.

TO THE EDITOR.

SIR,—“An Enquirer,” whose letter appeared in your issue of the 25th ultimo, asks me a series of questions on the subject of *Fish Manure for Tea Gardens*. I will reply *seriatim* :—

1st. To fish manure a tea garden of 50 acres.—This will cost about Rs. 150, or nearly one rupee per *bigha*.

2nd. Proportion of application. One to one and-a-half manure of rotten *poontee*, or any other kind of oily fish will be found sufficient to fertilize one *bigha*, that is, a handful of this manure is sufficient for one bush.

3rd. I have never enquired the price of fish-manure in the market, as whenever it was required we generally prepared it ourselves. I am therefore unable to say where it can be obtained.

4th. Where fish-manure was used. In a garden in Assam, also in one at Madras situated on the Hills (I omit names here) fish-manure was used to renovate the soil, as the out-turn of these two tea gardens had fallen off in flavour and quantity, though they had been well manipulated. The fish-manure proved effectual.

HEM CHUNDRA DUTTA.

December 7, 1885.

THE JUTE INDUSTRY.

TO THE EDITOR OF THE “STATESMAN.”

SIR,—The depression in jute stocks still continues; remedy after remedy is suggested, the usual want of unanimity exists; some let close for a time, that remedy fails; unless all are agreed, it could have but one result; half-time, or short hours, is then put forward, and as from the beginning of time, the under-current of petty jealousy that pervades all inter-European dealings in this country prevails, and again no unanimity. This state of affairs is bad enough, and the depreciation in value during the past two years has been terrible; but surely, if agents cannot agree in one common action, as regards the working of the various mills in their charge, they can be unanimous on the subject of the Government Jute Mills. It is a positive and crying shame that neither of themselves, nor through the Chamber of Commerce, have they made any representation regarding it, and it is intolerable, because not conducted either on a small scale, or with a view to make prisoners understand that the labour is punitive. During the Poojah holidays the Government opposition was in full swing; and can any one even in the Government service say that instructing persons to become skilled labourers is any punishment: is it a fact? It is reported that criminals that should be treated with the greatest severity, convicted of no ordinary crimes, are put on to work in the Government opposition Mill. Surely working hand looms is no punishment, and now when numbers of industrious hands are not only thrown out of employment, but can hardly keep body and soul together, convicted criminals, no matter what the offence, are being fed and clothed, sooner or later to be sent into the world with a sum of money to their credit, and further to glut the market with their skilled labour, and the produce of this very Mill is forced on the market, and sold to the highest bidder in competition with the labour of honest men. It is only in this country, where no one seems to be in authority that such scandalous work is allowed to exist. It would be more than instructive to know what class of criminals have lately been forced on to this Mill work; it would give some of the native papers a subject to write on, to see thousands of their honest countrymen barely able to exist, owing to the terrible depression in the jute trade and Government pampering criminals of a bad class to add further supplies to the present over-production. It is becoming positively appalling, the apathy that has come over investors; daily they see the shares in River Steam Companies

falling (every fall of Rs. 10 in India General means 5 lakhs). Jute stock is positively unsaleable, and yet this Government Mill is allowed placidly to continue its operations at a loss, and no one in authority takes any step to point out the enormity of the proceeding, and enormity it is. Every one knows connected with the industry, that with the strictest economy bags can only be made at a loss, and here we have a large Government Mill actually working and selling its product. On the face of these facts, and what is still more reprehensible, turning out time expired men as skilled labourers to compete with the honest industry of natives who have had during the last year to feel the results of the depressed trade. It would be tolerated in no other country in the world, and it shows conclusively how utterly blind and oblivious every official is to everything unconnected with his own work, and how he is trained up in the belief that opposition to every non-official industry is a sacred duty, and to listen for a moment to any honest objections to their system or procedure is to stamp you as an opponent to the true interests of the natives, and only guided by your rapacity; and Mr. Gladstone expressed it as "arrogant assertion;" and sufferers like myself are to sit still, and see a wholesale manufacture carried on at a dead loss by criminals of the worst class in direct opposition to my own trade. The Government Jute Mills are not self supporting; they cannot be, and no figures they can produce will prove to me that if they buy jute to-day, they can turn out into a marketable article except at a loss, and if they have the audacity to assert, as I believe they do, that they are working at a profit, I am sure any agent of a Calcutta Mill on an inspection of their books will prove to them the contrary. There was some sense in employing criminals to build Port and break-water; but it is a crime on the part of Government to assist in stifling an industry like the manufacture of jute in times like the present, and their competition is of the worst kind; they are answerable to no one, and their accounts are not submitted to the scrutiny of accountants accustomed to deal with mill returns and results. Fancy Bombay putting up with such an anomaly as this. I do not doubt their loyalty, but I am convinced if it had been continued in the face of such repeated remonstrances and warnings and promises from the head of the State, it would cease. The Alipore jail would long ago have been gutted, and it is such continued disregard of public feeling, much less offence against popular prejudice, that has been the cause of many a mill in the old country being levelled to the ground. Many statements have been furnished me with regard to the Alipore Mill as run by the Secretary of State for India, but there is no necessity in going below the surface; the mill exists, it turns out a large quantity of stuff, and it is sold regardless of market or consequences, and it should be and must be stopped, and every agent of a mill who permits it to continue without a remonstrance, not once but repeated, until Lord Ripon's promise is fulfilled, is not doing his duty. I have dwelt on the subject and will, with your permission, continue to refer to it until I awaken the Chamber of Commerce or the mill agents to the folly of permitting its continuance. Can any of them answer me this question? To what extent have the hand looms been increased lately, and is it a fact that within the last few months criminals of the very worst class have been put on to the work, because they were short-handed—in fact, were and are driving full power? Are there any statistics as to the outturn of this mill, or is the production sold and far more than outsiders are aware of, without being taken into the calculation of mill outturns? Will Government go on half time if all others agree? Does not this last question prove the impropriety of their connection with a trade that may require such an arrangement? How can they with their prisoners employed in such work? Their tendency is and has been to increase not by steam power but by hand power, and you will be told and led to believe such work is a punishment; a positive farce known to all, but it opens the door to any increase they may choose, and will they tell me such Superintendents as Mr. Beadon will give heed to any remonstrance? No, the evil has grown and is growing, and many who read this will say it is a fuss about a small affair; will such reader with this answer, supply me with the outturn from Alipore during 1883, 1884, and 1885, and say then if it is a fuss?

A JUTE SHAREHOLDER.

Editorial Notes.

In another column will be found the prospectus and regulations of the International Exhibition of Industry, Science, and Art to be held at Edinburgh in 1886. The executive committee are very anxious to have exhibits from India, and have expressed a hope that the exhibitors from the various presidencies at the London Exhibition may be induced to send duplicates of articles to that at Edinburgh.

THE Madras Government have sanctioned the removal of the Monthol fish-curing yard to a more favorable site at Madakara, about two miles south of Mahé. The new site is reported to promise well, as it is the residence of about 200 fishermen with seventeen deep sea-nets and thirty-four fishing boats, while the old one had but few fishermen resident in the vicinity, and was unfavorably situated for fish-curing purposes in a coconut tope.

THERE was an auction sale of Cinchona bark held at Madras, on the 5th ultimo. The total amount realised was Rs. 56,531. All the barks sold very well, compared with the prices obtained at the last sales, especially the Naduvatan renewed crown bark and the Dodabetta root and natural crown bark. Another point also worthy of note is that the price per pound in English money is higher in every case, excepting one, than that obtained for the same kind in the London market according to the last quotations.

WE understand that his Highness the Maharaja of Cooch-Bihar, with the view of gaining a proper representation of the Fauna and resources of his territory in the forthcoming Colonial and Indian Exhibition, has made a grant of £500, together with skins of animals and birds found in Cooch-Bihar; and the Government of India has commissioned Mr. Rowland Ward, F.G.S., the naturalist of Piccadilly, London, to produce from the material a picturesque trophy of great importance for the coming Exhibition. Probably other Indian Princes will, in like manner, illustrate their territories.

MR. THOMAS WARDLE, F.C.S., F.G.S., the well known authority on all matter relating to the manufacture and dyeing of silk was a passenger by the mail arriving in Bombay on the 8th instant, with instructions from the Royal Commission for the Colonial and Indian Exhibition of 1886 to visit the silk districts of India in order to make a collection of Indian silks, both raw and manufactured, with a view to stimulating the development of all the silk products of India and their utilisation in Europe. Our readers will remember the notices we recently published of Mr. Wardle's exertions in this connection. We suppose that Mr. Wardle will turn his attention chiefly to the *tussar* silk industry, which is indigenous to India, and which, under proper management, may be expected to achieve extraordinary results.

**

THE following is the report on the condition of the cotton and til crops in the N.-W. Provinces and Oudh, for the month of October 1885:—

Division.	Crop in full average condition.	Condition of Cotton Crop.	Condition of Til Crop.
Meerut	...	75	67
Rohilkhand	...	50	33
Agra	...	58	42
Allahabad	...	75	58
Benares	...	75	67
Jhansi	...	67	67
Tarai (District)	...	58	83
Lucknow	...	67	58
Silapore	...	42	33
Pyzabad	...	67	67
Koy Barrilly	...	67	58

**

THE Superintendent of the Madras Survey, Colonel H. T. Rogers, in a recent letter to the Madras Government, pointed out that the shortest time in which the revenue and topographical survey of the presidency can be completed is 16 years, and that the survey of extension of cultivation, the re-demarcation and re-survey of districts, which have never been permanently demarcated, and miscellaneous work of various kinds will extend this period to quite 20 years with the present establishment, and that it would therefore appear premature to prepare now any scheme for contracting the department to its lowest permanent limits.

The work remaining to be done is as follows:—

Original Survey—			
Revenue	...	16,278	square miles.
Topographical	...	19,391	"
Re-demarcation and Re-survey—			
Revenue	...	8,852	"
Extension of Cultivation—			
Revenue	...	1,247 52	"
Total	...	45,776 52	

THE following is Messrs. Lloyd and Carter's memo. of Indian Tea :—

FOR WEEK ENDING 12TH NOVEMBER 1885.

	Indian.	Ceylon.	Java.
Packages.	Packages.	Packages.	
Offered ...	23,194 ...	1,253 ...	1,107
Sold about ...	20,000 ...	1,253 ...	1,107

There has been rather less offered during the week, and the demand has been fairly steady, though occasionally thin undesirable parcels have gone a shade easier. Pekoes under 1s. do not attract notice, though cheap; good Pekoe Souchongs being preferred. A telegram from Calcutta, dated yesterday, states that the total export for the season to Great Britain will not exceed 64,000,000 lbs. (about the same as last season); from this amount will have to be deducted the cargo of the *Indus* which has become a total wreck. China teas keep very firm. To-day's auctions, amounting to 4,500 chests, have been postponed until to-morrow, owing to fog.

A CORRESPONDENT of one of our American exchanges, writing about an experiment tried by him with unleached wool ashes to prevent the ravages of the cabbage worm and the deposit of eggs on the plants by the "millers," says :

"I took dry, unleached wood ashes full strength and splashed right on top of each plant, from a half to a full stove shovel full, determined to kill the worms if it killed the cabbage (which was sure of total destruction any way, if no better remedy could be found than has been applied), and, to my satisfaction and almost astonishment, the first application proved a radical cure, killing almost instantly every worm touched by the ashes. I took pains to jar the plant, by hitting it lightly with my foot, to shake the ashes thoroughly between the leaves, to be sure to make soap of every worm. The plants were not only uninjured by the ashes, but started with new life and energy. The swarm of millers which had constantly hovered over the patch seemed to leave in disgust, and no further trouble was experienced for several weeks, but a rapid and unmolested growth of the plant ensued."

THE Superintendent of Stationery, Madras, has submitted the following memo. on the condition and prospects of paper manufacture in the Madras presidency :—

Paper is manufactured in the districts of Madras, Chingleput, Godavari, North Arcot, Madura, Cuddapah, Tinnevely and Coimbatore. The manufacture is for the most part done by hand, and the process is therefore rude, and the paper made coarse. The materials used in the manufacture are chiefly waste paper, old rags, gunny bags, hemp and aloes. Plantain leaves are also used in some places. There are lots of other materials available from which good paper can be made, such as cotton, rice, straw, bamboos, refuse of sugar-cane and grasses of various descriptions, but they are not used for want of suitable machinery. The quantities manufactured in each district are not known, but they cannot be large. The Stationery Department purchases from the manufacturers at Madras about 7,000 reams annually, and the papers so purchased are used for covers chiefly. There is no prospect of the manufacture improving unless machinery is introduced and manufacture undertaken on a large scale.

The Board of Revenue, in forwarding the above to Government, remarked that the samples furnished showed the paper to be generally of very inferior quality. A few samples from Madras town, North Arcot and Tinnevely are described as being suitable for ordinary covers; but the paper readily absorbs moisture and is much eaten by insects. "It is therefore unsuitable for official correspondence." Madras is, we think, very much behind the times in paper manufacture. Our Bengal mills turn out very creditable qualities of paper. For that matter, the mills at Lucknow do a very good business too, and the specimens of paper that we have seen turned out by the latter are certainly suitable "for official correspondence."

THE Dutch Colonists in Sumatra have discovered, hidden behind a belt of the densest jungle, petroleum wells which are expected, under proper management, to yield a handsome return. At the depth of one hundred feet, the wells begin to spout water, gas, and petroleum mixed. Deeper down, there is less water and more oil; and the enterprising Dutch engineers

have a notion, like Mr. Besant's hero in the *Golden Butterfly*, that they will, ere long, tap one of the greatest of earth's oil-tanks. No preparations, however, have yet been made to store the rush; and the product of the trial borings is given away to the Malays, who drive a large trade in it. A natural basin-like hollow collects the wastage from the wells; and a match thrown into this hollow leads to a general conflagration, which gives satisfactory proof of the purity of the petroleum. The only difficulty connected with the wells is their difficulty of access, for jungle has to be penetrated in places on all fours, through dense thickets of creepers and acres of fallen trees.

THE Calcutta *Journal of Medicine* publishes an important statement as to the efficacy of Cocaine, as a local application in the case of severe burns. The statement is taken from the *Practitioner*, and is as follows :

Dr. Weiss writes: On December 25th, I was called to Professor L—. An atomiser which he was using had exploded, the hot steam badly scalding the Professor's lips, nose, eyelids, cheeks, and forehead. The pain was so intense that I apprehended general convulsions. I sent for sundry topical remedies, amongst them a two-per-cent solution of *hydrochlorate of cocaine*. In the meanwhile I covered the injured parts with pieces of cloth dipped in olive oil; on the top of these I applied ice-water compresses renewing them every minute, without affording the slightest relief. When the medicaments arrived, I touched the injured part with a hair-pencil dipped in the cocaine solution. I had scarcely finished, when all pain had entirely vanished without any return. At my visit in the evening, I found the patient quite easy and in good spirits.

It would be of interest to learn that this simple remedy had been tried with success in the Calcutta hospitals.

THE Cashmere correspondent of a Bombay contemporary, writing from Srinagur, under date 25th November, says :—

The approach of the cold weather has brought back to us the earthquakes that did so much mischief and caused so much alarm during the greater part of the summer. Every evening this week there has been a shock, and sometimes one during the night, and occasionally in the day time. At six o'clock this evening there was a shock which sensibly affected the house and all that was in it; in a few seconds it was gone, but unpleasant memories have been aroused by these repeated visitations. The most severe of recent shocks was on the night of Sunday, the 15th, at about eleven o'clock; this shock was almost as severe as the first great shock in May last, and drove some persons out of their houses. There is a peculiarity now in the mode of working, if such a term may be used in reference to these subterranean shakings and eccentricities. Last night, for instance, the rumbling sound that precedes so many shocks took place four times without any shock or trembling of the earth; these noises could not be mistaken for thunder, for there was not a cloud in the sky and the moon is near the full. Again, during the stillness of the evening, not a breath of wind is stirring. A trembling is sometimes sensibly felt in the earth, but there is no shaking of the house, nor any noise like subdued thunder. What do these peculiar movements indicate?

SIR ALFRED LYALL is reported to have held an Agricultural Durbar at Lucknow on the 3rd instant, in connection with the Agricultural Exhibition—that is, a durbar for the reception of people interested in the agriculture of the province. Some fifty or sixty talukdars and zemindars from the North-West and Oudh, who had interested themselves in the promotion of agricultural improvements, were present. Prior to his Honor's arrival, several important agricultural matters were discussed, and resolutions were voted, and recorded. The native gentlemen invited to the Durbar were then presented in the usual way to the Lieutenant-Governor by Mr. Smeaton, Director of Agriculture and Commerce. His Honor addressed the Durbaris, thanked them for their voluntary labours during the past year in supplying the Director with monthly forecasts of the condition and prospects of the principal export crops, and hoped they would continue their assistance. He urged the prosecution of agricultural improvements, and trusted some substantial results would be forthcoming on the occasion of the next durbar. A full report of the proceedings, which were of no ordinary interest, will be found elsewhere.

On the 21st October last, the Dewan of Mysore delivered his usual annual address in which he reviewed the administration of the province during the past year. Amongst other matters he made the following statement regarding the collection and scrutiny of statistics :—

The immensity of the famine this year has brought to notice some defects in the present machinery for the collection and scrutiny of statistics—agricultural, vital, and economic. For a small province like Mysore, it may perhaps not be necessary to have a separate Department of Agriculture, but it is absolutely necessary to have at the head-quarters an officer of standing and experience, who could "collect and deal with the statistical returns relating to the weather, the agriculture, the health and the well-being of the people, and thus secure the most prompt and accurate knowledge attainable of a probable failure of crops, and of the extent and consequences of any failure that actually takes place." In ordinary times, this work may not be sufficient for a separate officer. It is therefore in contemplation to combine the office of Director of Statistics with that of the Inspector General of Police and of Forests and Plantations. In connection with Forest legislation, he added that it is proposed to place the Department under an Inspector General of Forests and Plantations. The Government are training three students in the Forest School at Dehra Doon for the post of Assistant Conservators, and it is proposed eventually to give an officer of this class to each district.

.

His remarks on the subject of pastures on the same occasion are of importance. He said :

The important subject of pasture reserves is also now engaging the attention of Government. In a country like Mysore where cattle-breeding is carried on to a large extent by the Government as well as by private individuals, the subject of pasture land is of the utmost importance. For the Government cattle, valuable pasture land has been reserved, and for private cattle the Survey Department has allotted to each village free gomal or pasture land, this allotment being supplemented yearly by the sale to the villagers of the right to graze on Government waste-land, which, in many places, is extensive. In ordinary seasons, the existing provision is understood to be sufficient. In years of scanty rain-fall, there is invariably a general cry against the insufficiency of the existing grazing provision, and all the District Officers and Amildars consulted, affirm that the cry is not without reason. The deficiency is generally met by temporarily placing the Reserve Forests at the disposal of villagers for the purpose of grazing, an arrangement inadequate in itself and not considered as a rule a safe one, as there is always a risk of the privilege being abused. It is, under the circumstances, proposed to make a permanent provision that may, to some extent, meet the requirements of good and bad years, and to make the ryot independent, as much as possible, of Government Reserved Forests. It is admitted that the present Amrut Mahal allotment is far in excess of what is actually utilized by the Government cattle, and it is therefore proposed to reduce it to some extent. When this is done, some of the surplus kavals would be utilized for fuel and pasture reserves, which could be thrown open to the public in exceptional years, while other surplus kavals could be placed at the disposal of the public on the moderate assessment of hulgaval tenure, and on the distinct understanding of liability to enhanced assessment for lands brought under cultivation. The experiment of preserving green fodder in silos is being carried on a large scale by the Military Secretary, who is in hopes of being able to report favourably upon it at an early date. The report, when received, will be published in the *Gazette* in English and Canarese.

.

The following is the report on the state of the season and prospects of the crops for the week ending 2nd December 1885 :—With the exception of the Madras district of Madras and the Dibrugarh district of Assam, no rain has been reported from any part of India during the past week. In the Madras presidency prospects are generally fair, and continue favourable in Bellary and Anantapore. In Mysore the standing crops are in good condition, and harvesting of ragi and sowing of gram, *jowari*, and paddy continue. Water and pasturage are abundant, but cattle-disease is reported from three districts. In Coorg the season promises well. In parts of the Poona, Nasik, Khanesh and Ahmednugger districts of the Bombay presidency, rain is wanted for *rahi* crops. Reaping of the *khari* and sowing of the *rabi* crops continue in most districts. In the Berar and Hyderabad the crops promise well. In the Central India

States and in most of the Rajpootana States the prospects of the crops are good ; but in Sirohi, Meywar, Kerauli, and Dholpore tanks and wells are low. Prospects continue favourable in the Central Provinces and the *rabi* sowings are complete, except in the Chhattisgarh division, and the *khari* harvest is in active progress. In parts of the Punjab, rain is much needed ; *rabi* operations are in general progress. In the North-Western Provinces and Oudh the *rabi* promises well, but more rain would be beneficial for sowings. The weather continues reasonable. Some damage has been caused to crops in East Bengal by the rain and wind of the previous week. The *aman* harvest promises a good outturn and the *rabi* crops are coming up well, though in parts of Behar and Hazaribagh more rain would be beneficial for these and for poppy. Prospects continue good in Assam. No report has been received from British Burmah for the week under notice. The public health continues fair. Prices are falling in Coorg and are fluctuating in Mysore ; elsewhere they are generally steady. In Bengal the price of rice is lower than last year in almost all districts.

.

It may not be generally known that cotton of excellent quality is largely grown in the territory of H. H. the Maharaja of Hill Tipperah ; and that the produce is eagerly bought up by Calcutta firms for export to France, where it is utilized in the manufacture of broadcloth. The cotton is subject to an export duty, which realizes a considerable revenue ; and the result could be still more favourable to the finances of the State if the tariff were lowered, and direct collections substituted for the present system of farms. The Director of Agriculture recently enquired whether the khakee-coloured variety was produced, stating that 4 annas per pound would be given for cotton of that colour by the Superintendent of the Buxar Central Jail. Samples of khakee-coloured cotton were promptly furnished to the latter officer, and he was informed that an unlimited supply could be given in a year or two, if sufficient encouragement were given to the cultivators. His report on the samples is not very encouraging, though it indicates, pretty clearly, the line which reform should take. He writes : "The khakee cotton is of an uniform colour but is rather pale, and as the staple is rather short, it will not make up by itself, and will have to be mixed with darker and better stapled stuff. If the State is adapted for growing cotton, I would recommend China Nankin seeds being sown, as that cotton is darker in colour, of a good long staple, besides being silky to the touch and in appearance." In view of the importance to the British army of a constant supply of cotton, innocent of the horrible native dye-stuffs, it might be worth while to supply cultivators with the China seed. Immense tracts exist in the hill territory, admirably adapted for the growth of every variety of cotton, and the reforms, which we understand are contemplated in the fiscal policy of the State, should give a great impetus to the cultivation of this important staple.

.

It would appear, from a paragraph published in the last number of the *Farmers' Review* to hand, that the large amount of wheat "in sight," that is, stored in elevators or in transit by rail or vessel, has more than anything else depressed the price of wheat in America and Europe. It is said to have increased since the harvest began from about 40,000,000 bushels to nearly or quite 60,000,000 bushels at this time, in spite of consumption and export. The recent large increase in "visible wheat" is largely due to the farmers in the north-western parts of the United States storing their wheat as they threshed it in the elevators of the railroad companies, taking receipts for it according to grade, and deliverable to them at their pleasure. This, says the *Review*, while a seeming advantage and convenience to them, has worked to their injury by so largely increasing the amount of "wheat in sight," as to cause the present break in the market by which a large share of the recent advance has been lost. It is safe to assume that if the wheat which the farmers have stored in the elevators had been stored on the farms, and kept "out of sight," this break would not have occurred. But it is difficult to sustain prices with 50,000,000 bushels in sight, and the amount showing a steady increase from week to week. In spite of this showing, the fact remains that the supply of wheat the world over is a short one, and this fact must sooner or later tell on prices, which, as we think, must advance materially before another crop is grown.

THE appeal made by the Chamber of Commerce to the owners of our local Jute Mills to reduce their time of working to four days in the week, seems to us so wise and reasonable, that we cannot but hope it will be responded to by a unanimous resolution of the Mills to act upon the advice. There is plainly but one remedy for the present state of matters within the reach of the Mills, and they should recognize this fact and act upon it, just as they would if the Mills were owned by a single Company, which found itself producing a larger quantity of goods than its customers could take off its hands. It seems to be admitted by every one that if the Mills work full time their production is in excess of the demand, and that there are no markets to which the Mills can look for the consumption of this excess. In these circumstances, the Mills should do just what would be done if they were the property of a single owner. The proprietor would face the fact that he had unduly extended his machinery, and pending the development of a natural and remunerative demand for his goods, he would limit his production to the quantity that was really in demand. Nearly the whole of the Mill Companies, we believe, see the wisdom of this course, but they are embarrassed by the refusal of one or two of their number—who are perhaps working under peculiarly favorable conditions—to join the movement. We may perhaps without offence remind these Companies, that there is a stronger tendency every day in the scientific world, to repudiate as unsound the purely selfish theories on which modern political economy has been based, and to recognise the fact that the higher wisdom which teaches us to “Look not every man upon his own things, but every man also upon the things of others” is alone consistent with true and healthful progress. It may not be reasonable or just that a hard-and-fast line of four days per week should be drawn as a provisional remedy for the evil to be adopted by all the Mills alike, but no objection of this order should prove fatal to the movement, if owners are but wise enough to recognize the fact that generous co-operation for a common purpose, and not mere competition, is the proper remedy for the existing state of matters. It is clear that the industry has, for the moment, been unduly extended, and the object of all parties should be to tide over the period that must elapse, before matters have righted themselves, with as little common sacrifice as possible.

THE following figures from the Board of Trade returns for October 1885, we extract from a home contemporary :—

The Board of Trade Returns for October and the ten months ended 31st October have just been published, and show that the value of our imports during the month amounted to £29,757,327, against £31,097,132 in 1884, and £35,833,755 in 1883, being a decrease of 4·3 per cent as compared with 1884, and of 17 per cent as compared with 1883. The total for the ten months is £312,812,458, against £325,958,226 in 1884, and £355,123,514 in 1883—a decrease of 4 per cent and 11·9 per cent, respectively. The increase this month in the foreign export trade is almost entirely due to the larger shipments of wool to the Continent and the United States, and as the total has risen from 12,455,055 lbs., valued at £618,373, to 31,915,278 lbs., valued at £1,496,070, the increase is at once accounted for. In the import account, animals, living (for food), have declined from £953,823, to £601,978, or 36·9 per cent, owing to the combined circumstances of lower numbers and lessened values; articles of food and drink, admitted duty free, have declined from £9,903,870 to £9,770,280, or 1·3 per cent, and those on which duties are levied from £3,125,281 to £2,715,079, or 13·1 per cent, while tobacco has increased from £220,801 to £401,730, or nearly 82 per cent. Among the free imports wheat has increased from 3,826,636 cwt. to 4,692,664 cwt., oats from 895,990 cwt. to 1,200,022 cwt., and Indian corn from 1,303,872 cwt. to 2,658,313 cwt., while wheat flour has decreased from 1,243,442 cwt. to 1,104,760 cwt., and barley from 2,220,604 cwt. to 1,531,141 cwt., peas and beans also showing for smaller quantities. Bacon and hams have been more largely imported, but at lower prices, the latter with an increase of 4,748 cwt., being less in value by £15,896, and the same remark applies to many other articles of food; but unrefined sugar is certainly dearer, as, although the quantity has dropped from 1,233,028 cwt. to 971,674 cwt., the value has only fallen from £766,806 to £711,638.

With regard to the British exports of the month, there is an improvement shown in articles of food and drink, most of the items in this class having been more largely shipped, and the total value has consequently increased from £1,123,251 to £1,174,065, or 4·5 per cent. Animals, living, have declined from £17,275 to £11,597, or 11·4 per cent; and that notwithstanding the large shipments of British sheep's wool, especially to the United States.

The detailed figures with regard to the principal imports of raw materials and food are as follow :—

IMPORTS FOR OCTOBER.

Articles.	Quantities.	Inc. or Dec. per cent.	Value.	Inc. or Dec. per cent.
Cotton, raw	748,936 cwts.	26·98 d.	£2,098,747	28·20 d.
Flax	103,217 cwts.	9·87 d.	179,165	13·72 d.
Hemp	84,149 cwts.	28·85 d.	126,686	28·71 d.
Jute	243,336 cwts.	8·89 d.	148,351	1·21 d.
Silk, raw	249,926 lbs.	53·18 d.	179,682	50·93 d.
Wool	771,426 loads	17·76 d.	1,764,623	16·78 d.
Wool	17,680,411 lbs.	2·44 d.	793,237	3·97 d.

ARTICLES OF FOOD, &c.

	1884.	1885.
Animals	£953,823	£601,978
Bacon	423,356	467,309
Beef	237,534	219,558
Butter	1,235,136	917,733
Cheese	556,719	370,501
Corn	3,800,255	4,138,488
Eggs	228,783	202,917
Fish	111,082	171,511
Hams	133,491	117,605
Lard	70,933	144,708
Meat	123,977	172,272
Pork	39,583	42,073
Potatoes	11,810	19,077
Poultry	70,454	71,422
Rice	251,224	262,779
Total	£3,253,190	£7,919,931

* *

THE following is a summary of the weather report for October last :—

With the exception of North-Western India, where the fine weather which set in in September continued uninterruptedly, the weather, though unmarked by any serious disturbance, has been in a generally unsettled state, and about the 12th assumed a somewhat threatening appearance over the Bay.

Throughout the month, the skies of Upper India and a large part of the Central Provinces were almost cloudless, and there was an almost total absence of rain. In nearly all other parts of India there was general rain throughout. On the western side of the peninsula, including Berar and Khandesh, rain fell daily until about the 12th, after which it ceased for about 12 days, when a slight and partial fall again took place on the South Concan coast. The winds in Western India were occasionally variable, but, on the whole, maintained their normal east-north-easterly direction down the valleys of the Nerbudda and Taptee, and a south-westerly direction on the South Concan coast. Further southward in Malabar and in the interior of the peninsula, in the same latitude, the break noticed above was hardly felt, and more or less rain fell throughout. In Madras also rain fell on almost every day; but the burst of heavy rain, which usually ushers in the autumn rains of the Carnatic, has not occurred. On the 29th the observer at Madras reported the setting in of the monsoon, but the rainfall on that day was slight, and a fall of 3½ inches on the 30th appears to have been due to local conditions. The rainfall has been below the average. Round the head of the Bay, and also in Eastern Bengal, Assam and Burmah, there were frequent showers about the middle of the month, and again between the 21st and 25th; but at other times, the weather was generally fair and abnormally warm.

The table at the close of the summary shows that, from the Punjab south-eastward down the Gangetic plain, as far as North Bengal and also in the Indus Valley, the rainfall of the month was insignificant. In Assam, Lower Bengal, round the head of the Bay, and westward into the Central Provinces, there was more rain; but here also, as well as in the Carnatic and Burmah, it was below the average. In the western parts of the country and in the central and southern parts of the peninsula, viz., from Southern Rajpootana to Mysore, Malabar and Ceylon, there was a strongly marked excess—relatively greatest in the Berars and Khandesh, but very considerable in some of the other districts also.

On the 12th, a very decided fall of the barometer took place, not only over the Bay but throughout the whole of the Indian area, with the exception of the north-west. At the same time, the winds which, on the previous day, had been irregular and variable, became cyclonic round the Bay—blowing from west at Negapatam and Colombo; from south at Diamond Island; from north-east in Aikan and Lower Bengal; and from north north west along the west coast of the Bay between Gopalpore and Madras. It was evident that a large low-pressure area had been formed over the Bay. The next day the reports showed the barometer still falling, and that the storm area had travelled northward to the neighbourhood of Orissa. Reports from ships, subsequently received, showed that very rough weather had been experienced in the Bay, but the storm seems to have broken up without reaching the shore.

The pressure has been generally above the average throughout the month. The excess was considerable in parts of the peninsula, in Lower Bengal and Guzerat, but it decreased to the north-west, and at some stations in the Punjab was evanescent. Temperature was also generally above the average, except in Madras, at one or two stations in Bengal and Assam, and at Secunderabad, Ajmere, Simla, and Rawul Pindie. In Northern India, owing to the early cessation of the rains, October was a warm month, and the range between the day and night temperatures greater than usual. The relative humidity was, on the whole, below the average, except in the peninsula, Northern Bengal, and Assam. The winds have apparently been less regular than usual, and the low pressures which have prevailed over the Bay, in conjunction with the high pressures over the peninsula have caused dry north-westerly and westerly winds to prevail on the Carnatic coast instead of the normal moist northerly and north-north-easterly winds. Hitherto the November weather has been of a similar character, and the rainfall of the past fortnight, at several Carnatic stations (not at Madras itself) has been short of the average.

PROPOSED AGRICULTURAL OPERATIONS IN THE MADRAS PRESIDENCY.

Not long ago we alluded to the programme, published by the Government of Madras, which it was proposed to carry out in respect to agricultural operations in the Southern Presidency. In that it was stated that "our knowledge of Indian crops is too limited as yet for useful experiments." In another recently published G.O. on the subject of making experiments in diversifying the cropping of the irrigated area in the Presidency which is now almost solely devoted to paddy, we find the same Government stating that "there is no need to await more knowledge as to our Indian crops." We wonder what it all means. In the latter case, Mr. Benson seems to have been responsible for raising the point. The Director of Agriculture evidently hopes to acquire the knowledge by means of the experiments now proposed. The Board of Revenue state that it "can best be acquired by close study of actual conditions, if it is not found to be possessed by most middle-aged ryots and landholders." The Madras Government agree with the Director of Agriculture.

The Saidapet farm was closed because our knowledge of Indian crops is too limited for useful experiments. Now the Madras Government say, "it is unsatisfactory, after twenty years' experiments at Saidapet, to find the plea of want of knowledge put forward." Mr. Benson evidently wants more knowledge of our Indian crops. Without a clear definition of the description of information he wishes for, we are unable to say whether his plea is a good one, or whether the strictures passed thereon are justifiable. We are very well assured, however, from our knowledge of Mr. Benson's reports and book, "The Saidapet Farm Manual," that his knowledge of our Indian crops must be extensive. And was he not long since placed in charge of the Agricultural College at Madras? Would he have been placed in such a position, if his knowledge on this subject had not been the best obtainable, when Mr. Robertson was absent from India? The question then arises, what kind of knowledge can it be that Mr. Benson wants? As he said the other day, if it be practical knowledge of our crops, such as is to be obtained in the field, we consider the plea to be one meriting the censure of Government on those who put it forward. But we are inclined to believe that it must be a more intimate and exact knowledge than the longest and widest experience in the field

can afford, which Mr. Benson asks for. In fact, we believe him to ask for, what we ourselves feel the want of, such knowledge as is only to be obtained by agricultural research, scientifically conducted. Such a study of the life-history and habits of our plants which can only be conducted in the laboratory and greenhouse, and which no amount of observation in the field can equal as affording a basis for sound and unassailable reasoning, or for the construction of healthy and vigorous, or the modification of empirical, systems of agriculture, when combined with a complete study of the two governing factors in all agricultural processes—soil and climate.

We must admit that as regards knowledge of the life-history, feeding-grounds, special forms of food affected by our common and industrial crops, we are in India lamentably deficient. We have, it is true, a certain amount of information on these points, as applied to plants generally, but they have never been studied under Indian conditions, nor with reference to Indian crops. No institution exists, nor has existed in India, organised for this special purpose; and even the best educated and trained of our agricultural officers can only apply, as far as possible, the general results of agricultural research in Europe to the crops and conditions with which they have to deal.

There is work for many agricultural chemists in India, and we wonder when the recommendations of the Conference, held in this city two years ago, are to be carried out. Partial and incomplete though they were, they at least would have given us some hope that some of the many great agricultural problems now before us in India, would have been placed in the way of settlement, had they been carried out. Without a basis of scientific research, no agricultural enquiry can be soundly started. No such research has been begun. No means are available for it. Well may the cry be, "We want knowledge." The Madras Government intended to have some experiments made to determine whether the water now used in raising rice cannot be economised; but say, that it is unnecessary first to determine "what is the least amount of water required to raise a remunerative crop of paddy." Unless the latter point is determined, we fail to see how it can be determined whether the experiments have proved an economy or not. That experiments to decide the point are necessary, and urgently necessary, no one with any knowledge of the manner in which water is used in rice cultivation can for a moment doubt. We therefore regret greatly the resolve of Government to allow an opportunity for carrying out experiments of such incalculable value and importance to the country to slip away.

To pass on: the Government do not think it to be necessary to provide any one to conduct and record the progress of the experiments, but would leave all this to private enterprise. This shows, either great faith in the enterprise and generosity of the ryots and landholders of Southern India, or great ignorance of the labor and time required to conduct and observe the progress of any agricultural experiments. We have no reason to suppose that, even in Madras, there are any number, if any, land holders able and willing to undertake such a laborious task. Even in wealthy England, there are few landlords—not simple landholders, be it said—who would face the trouble and expense of such a set of experiments as is sketched out by the Madras Government. If Madras can produce many such men, we must congratulate Mr. Robertson on the result of his labors. They have been successful far beyond any possible expectations he could have had.

IMPREGNATION OF TIMBER.—I.

THE impregnation of timber is a matter of great importance in this country, and one to which the promoters of our Nilgiri-Rigi Railway will have to turn their earnest attention if they wish the sleepers of this much desired line to be permanent and durable. We will endeavour to give an exhaustive description of the best methods of impregnation.

Timber consists of fibre and sap. The former is an organic combination of carbon, hydrogen, and oxygen. The latter is a mixture of water and colouring matter, fats, ethereal oils, resins, tannin, gum, mucous, starch, sugar, organic and inorganic salts, and albuminous substances. Timber is liable to destruction

by insects and by decomposition. The composition of the sap commences first, and the sap communicates the decomposition to the fibre. The fibre itself is, however, not free from the liability to decomposition. In damp air chemically pure fibre decomposes. When linen or cotton cloth is bleached, the colouring substances are just oxidised with a small amount of the fibre, which is the same fibre as that of wood. After the colouring matter has been destroyed, and nothing is left but the pure fibre, the latter commences to decompose, and unless the bleaching process were stopped, the cloth would be wholly ruined. Hemp fibre is nearly pure, and yet hempen ropes have to be protected against wet by means of tar. Thus it is clear from these examples that, even suppose the sap to have been removed or rendered harmless, the woody fibre itself if not protected, is still liable to decomposition, although of course in a much smaller degree than when full of decomposing sap. Damp with simultaneous access of air is most injurious to the wood as it promotes decomposition. Precautions are taken when felling timber that it should contain as little sap as possible. In Europe, timber is felled in winter, and the trees are allowed to lie for some time with the branches and leaves on them, so that the budding which takes place the following spring will exhaust the fluid remaining in the stem. For a similar purpose peeling off the bark of the living tree some time before felling has been recommended. After timber has been felled it has to be seasoned. During the seasoning process, some substances contained in the wood not only lose their water, but also in a great measure their hygroscopic property. If after once having been dried or seasoned the wood becomes wet again, it dries much sooner. Wood has also been seasoned by artificial heat. This process is sometimes very useful, but it requires care: otherwise the wood will crack and split. The seasoning by artificial heat has been adopted in connection with impregnation. Wood is not only mechanically injured, but actually decomposed at a temperature of 300° . If, after seasoning, the wood is protected from moisture, it will of course remain unaltered for a considerable time, and a superficial coating is all that is required to render it still less liable to decomposition. It is wood exposed to the open air and to all atmospheric changes which requires special protection, and for the sake of which the system of impregnation has been introduced. Railway sleepers are not only exposed to the rain and sun in succession, but they also have to lie on the ground from which they imbibe moisture. To protect them in some measure, care is taken that they are bedded in a good ballast, which allows the rain-water to drain off quickly and decrease the absorption of moisture from below. Coatings should, of course, only be applied to well seasoned wood, and it is unnecessary to explain that green or wet wood when coated over will not be able to dry and must therefore soon decay. A completely air-tight coating would preserve the wood for ever against any influence; but this is not possible. Wood has been boiled in tallow to give it an impervious coating; but it was a failure. Boiled coal-tar, free from ammonia, forms a very valuable protection to the wood. The coating of coal-tar can be repeated until the tar has penetrated the surface of the wood to the depth of half an inch. A very good substance for coating timber is also a solution of resin in linseed oil. Silicate of soda gives also a good protection. A mere surface coating of the wood is also a good external protection. It prevents decomposition commencing from the outside. In many cases superficial coatings are used with effect for keeping off white-ants. In Burmah, for instance, the timber of wooden structures is coated with petroleum as a protection against white-ants, but the process has to be repeated every year. The ends of wooden rafters have been dipped into coal-tar and the access of white-ants from the walls to the rafters has thereby been prevented. A coating composed of vegetable extract called "gutta gambier" with dammer oil and lime has been found effective against white-ants. Painting the wood with a solution of sulphate of copper has also been practiced. To protect wood which has to withstand wind and weather, something more than mere seasoning and coating is required. It must be altered constitutionally. This is done in two ways—by the removal of the sap, and by the addition to the wood of a new integral part in the shape of an antiseptic substance.

As the antiseptic substance as a rule is capable of combining with the albumen of the sap, thus rendering the latter harmless, the expulsion of the sap can in most cases be dispensed with. There is one method which will be specially explained hereafter, where the expulsion of the sap and the addition of the antiseptic substance take place simultaneously. Independently of this latter method, the sap may be expelled by various means. Wood will lose a great part of its sap by long continued soaking in stagnant, or still better, running water. Steaming is a quicker process, but not much resorted to, because the wood is found to deteriorate. Heating the wood by means of dry air is preferred to steaming. This does not remove the solid contents of the sap, but it renders them less dangerous, because the albumen is coagulated by the high temperature. Albumen coagulates at 167° . Antiseptic substances are also necessary for the preservation of the fibre even after the sap has been rendered harmless: because, as has been already explained, the fibre is in itself subject to decomposition. The following substances have been used or proposed for impregnation:—Creosote of commerce which is made from coal-tar, carbolic acid in an alkaline solution, raw-wood creosote, raw acetate of iron, sulphate of copper, chloride of zinc, sulphate of zinc, perchloride of mercury or corrosive sublimate, chloride of sodium or common salt, sulphate of soda, saltpetre, borax, sulphate of iron, and arsenic.

The creosote of commerce and the raw-wood creosote are oily substances and are used by themselves, whilst all the rest of the foregoing substances are used in aqueous solutions. The creosote of chemists is procured by the distillation of wood, and it is also contained in wood-smoke. A substance very similar to the genuine creosote is contained in coal-tar, and this latter substance in its pure state is the so-called carbolic acid. Genuine creosote is at ordinary temperatures a fluid, whilst carbolic acid is a solid. Carbolic acid exists as an article of commerce not only in a crystalline state of comparative purity, but also in a fluid state, being kept in solution by various tar oils. This fluid mixture of tar oils and carbolic acid is the creosote of commerce. It is not strictly correct to call it creosote, because the name of creosote was originally given to the antiseptic substance of the wood-tar only, but as the name is generally applied, it is not expedient to make an exception here. The simple term creosote is therefore used in referring to the product of coal-tar, whilst if the product obtained from wood-tar is spoken of, the expression "genuine creosote" or "wood creosote" is made use of. The two substances, wood creosote and carbolic acid, resemble each other so much, that for many years their identity has been maintained. There are, however, reactions which clearly mark them as different substances. While carbolic acid is solid at ordinary temperatures, wood creosote has only been obtained in a solid state at a temperature below freezing point. Further, the wood creosote has the characteristic smell of wood smoke, whilst carbolic acid has a different smell. Wood creosote boils at 397° , whilst carbolic acid boils at 303° . The density of both substances is slightly above that of water. Both are little soluble in water, but mix in all proportions with alcohol and ether. Both coagulate albumen readily, a fact which explains to some extent their preserving properties. Both combine readily with alkalis, and in the case of both substances this property is made use of in separating them from other more neutral oils of wood and coal tars. Carbolic acid has also been combined with alkali for the purpose of preparing an aqueous solution for the impregnation of wood. The dry distillation of wood yields, besides charcoal and gas, a heavy tar, and floating above the tar, an aqueous solution of acetic acid and of other substances. This solution used to be called raw pyroligneous acid. This acid, when purified, proves, however, to be identical with acetic acid. The raw acid contains much wood spirit and 1 per cent of creosote. The impure acid in combination with iron is used for the impregnation of wood. This is what is meant by the raw acetate of iron, enumerated amongst the antiseptic substances. The tar is distilled a second time, when oils, first lighter, then heavier than water, are separated from the pitch. The heavier oils represent the raw wood creosote. For chemical purposes pure wood creosote is prepared from his raw material by repeated distillations, combination of the

wood creosote with alkali, red decomposition with sulphuric acid, &c. Coal yields, besides coke and gas, also a watery and an oily fluid. The former contains principally ammonia, the latter is subjected again to distillation. First more volatile oils are distilled, and with them benzine. At a temperature ranging between 150° and 200° the oils containing carbolic acid are distilled. The mixture of these latter oils and the carbolic acid constitutes the raw creosote of commerce. For the purpose of obtaining chemically pure carbolic acid, repeated distillations are carried on during which the carbolic acid is combined with lime and separated by muriatic acid, and then again combined with oxide of lead and set free by muriatic acid, &c. The dry distillation of wood yields products in something like the following proportions :—

Charcoal	25 per cent.
Wood-tar	7 "
Water with Acetic Acid, &c.	50 "
Gas	12 "
Loss	6 "
Total			... 100 per cent.

Pines and firs being more resinous, yield up to 14 per cent of tar. Wood tar re-distilled yields half of its quantity in pitch and half in volatile substances. The volatile substances consist to a great extent of creosote. The quantity of raw creosote in the wood-tar is on an average equal to 3 per cent of the wood originally employed, and the quantity of pure wood creosote in the wood tar is on an average equal to at least 1 per cent of the wood originally employed. The raw acetic acid also contains 1 per cent of wood creosote. To make a solution of raw acetate of iron, old iron is thrown into the raw acetic acid, in which a sufficient quantity of the iron dissolves to neutralise all the acid. The solution of raw acetic acid is used for the impregnation of timber chiefly on account of the creosote it contains. Thus two kinds of materials for impregnation are obtained from the dry distillation of wood—(1) the oily substance with much creosote; (2) the watery solution of acetate of iron with a small proportion of creosote. The latter material has not yet been generally approved of as a powerful antiseptic. During the manufacture of gas from coal, the following products are obtained :—

Coke	70 per cent.
Tar	6 "
Ammoniacal liquid	6 "
Gas	12 "
Loss	6 "
Total			... 100 per cent.

The specific gravity of coal-tar is 1.016. When re-distilled, it yields 25 per cent of volatile oils which can again be separated into lighter and heavier products. The former contain benzine, the latter contain carbolic acid, and they constitute the raw creosote of commerce. The quantity of pure carbolic acid contained in the whole of the tar is not less than 3 per cent. The quantity of carbolic acid in the creosote of commerce is sometimes very small indeed. For purposes of impregnation the proportion of carbolic acid ought to be less than 8 or 10 per cent. Creosote can be tested as to the proportion of carbolic acid it contains by a very simple process. The creosote is placed in a graduated glass tube. A solution of caustic alkali of a strength of 10 per cent is added, the whole well shaken, and afterwards allowed to settle. At the bottom unaltered alkali solution will be found; above this a syrup-like combination of carbolic acid with the alkali, and last the undecomposed volatile oils. The diminution of volume which the volatile oils have suffered, indicates the quantity of carbolic acid. Peat and lignite yield similar products to those of wood and coal. Peat gives about 7 per cent of tar, and 40 per cent of ammoniacal water. Lignite gives about 7 per cent of tar, and 30 per cent of ammoniacal water. These tars contain large quantities of either creosote or carbolic acid. Oil from bituminous shales contains also a substance similar to, although not quite identical with, either wood creosote or carbolic acid. Creosote of commerce is the most important substance for the impregnation of wood. Not only is the carbolic acid

which it contains a powerful antiseptic, but the tar oils also which keep the carbolic acid in solution are a most valuable protection of the woody fibre against damp. Creosote is also cheap and procurable in large quantities, so that it is well adapted for use on a large scale. Carbolic acid has been used in combination with alkalis in aqueous solution as a substance for impregnation. After the first impregnation with the carbolic acid salt, the wood has been saturated with a solution of sulphate of iron. This has the effect of causing free oxide of iron to be deposited in the pores of the wood, and of setting the carbolic acid free from the alkali. This material has the advantage that it can be used with water, but it is certainly a pity to lose the services of the tar oils, which accompany the carbolic acid in the creosote. The raw-wood creosote as an antiseptic for the preservation of wood is in no way inferior to the creosote of commerce. On the contrary, the raw-wood creosote contains much more really antiseptic substances than the creosote of commerce does. It is, however, very expensive and scarcely procurable in quantities large enough for purposes of impregnation. Raw acetate of iron can be used in aqueous solution, and this solution is able to take up a large proportion of wood creosote, which latter may thus be brought into the wood simultaneously with the iron salt. This substance is costly, and the results are questionable. The antiseptic qualities of sulphate of copper have been proved beyond a doubt, and it is very extensively used. There are instances where the impregnation of wood with sulphate of copper has failed. It is, however, unfair to ascribe all failures to the substance itself. Mineral salts when used as antiseptics have deficiencies from which creosote is free, but otherwise sulphate of copper is a good material. Sulphate of copper is used in solutions, with 1 to 2 per cent of the salt.

Miscellaneous Items.

CONSIDERABLE fiscal changes are taking place in Java. The import duties have been increased, and the export duties on sugar reduced by half, on coffee by two-thirds, and tea is made duty free.

MR. JETANGHIR FRAMJEE LALLIE, Veterinary Surgeon, has been appointed to take charge of the Bai Sakarbai Dinshaw Petit Hospital for Animals, which was opened a few days ago, for the purpose of giving curative treatment to diseased working animals gratis. A fee of three annas per bullock per day and six annas per horse will be charged to cover the cost of feeding.

CAPTAIN DONNAN, the Superintendent of Pearl Fisheries in Ceylon, has recently visited Sillavattural. His mission has been unsuccessful. He found all the oysters, in the experimental bank on the reef, dead, with the exception of a few which looked very seedy, and had not grown a bit since they were put into the bank in March last. Captain Donnan fully expected that pearl oysters would have lived and thriven in that bank as well as anywhere, and as they have not, he is very doubtful of the success of preserving them anywhere off their "natural beds."

ONE of the most noticeable features of the Sonepore Fair was Messrs. Jessop and Co.'s tent, in which were exhibited a number of agricultural implements and pumps. During the three great days of the fair, natives flocked in thousands to inspect this show, which appealed to their natural instincts as farmers, and displayed considerable interest in the numerous machines. Some of the wealthy zemindars made considerable purchases, and we are informed by Mr. Rainford, who represented Messrs. Jessop and Co., that orders were given for some 250 "Hindustan" ploughs. These admirable implements cannot fail to command an enormous sale when they become better known and appreciated by those interested in agriculture in this country. The testimony of those who have used them is entirely in their favour, and to this we can add our personal tribute of praise. We take this opportunity of warning the public against buying inferior ploughs of similar construction to the "Hindustan," which are now being offered for sale in certain districts, and which cannot fail to bring discredit on the genuine article.—*Indian Planter's Gazette.*

We learn that, amongst the exhibits to be sent from Madras to the London Exhibition are several sketches in ink of archaeological remains in the Presidency executed by the native draughtsmen attached to the Archaeological Survey of Southern India. The drawings have been finished in a most elaborate manner, the lights and shades of the sculptured portions being so brought out in bold relief as to form a faithful delineation of the originals. It is considered that, whilst forming very good examples of art and archaeology, they will at the same time afford people at home an opportunity of seeing for themselves to what excellence Indian draughtsmen of the present day can rise when under proper tuition and supervision.

LIEUTENANT GREELY, of the American Polar Expedition, delivered lately an address to an agricultural society at Pittsfield, in Massachusetts, in which he mentioned that during his Arctic exploration he had passed through a district in which there were numerous wild sheep having large heads, great horns like oxen, and tails resembling those of horses. Their fleece was of the finest and thickest wool, almost surpassing that of the merino. He observed that in New England there were often complaints of the difficulty of saving the lives of delicate beasts during a severe winter, and he was of opinion that it would be well worth while to make an experiment in acclimatization with those polar sheep, which thrive in a region where there is no shelter for them against the rigours of the Arctic winter.

GEOLOGICAL students will remember that last year much interest was caused by the announcement that human footprints had been discovered in the solid rock in a quarry over Lake Managua, in the territory of Nicaragua. The interest was increased by the statement that those footprints had been overlaid by 11 different layers of stone, extending to a depth of 4 metres. This seemed to indicate an antiquity for our race quite transcending all conjecture hitherto hazarded. An Austrian gentleman, Herr H. E. Low, has obtained and forwarded to the Imperial Museum in Vienna, 12 large stone slabs bearing those footprints. They are about three-quarters of a metre square, and weigh altogether 35 centners. They can now be inspected by European geologists. The footprints are sunk into the stone to a depth of from 8 to 10 centimetres. The stone itself is a porous volcanic tufa, and the superincumbent layers, which had been removed for building purposes, were all of a more or less solid volcanic conglomerate. The footprints are very conspicuous, and seem to be those of three distinct persons, one of whom was a child. It is stated that in one of the overlying strata, impressions of leaves were very numerous, and conspicuous. Unfortunately, no specimens of this have been forwarded to Vienna. But it may be safely said that it would be rash to infer an extraordinary antiquity for those footprints from the fact that they have been covered over by several layers of stone to a considerable depth, which might have been deposited by a succession of volcanic eruptions.

Selections.

INTERNATIONAL EXHIBITION OF INDUSTRY, SCIENCE, AND ART TO BE HELD AT EDINBURGH IN 1886.

REGULATIONS FOR EXHIBITORS.

1. An international Exhibition of Industry, Science, and Art, under the patronage of her Majesty the Queen, will be held in Edinburgh in 1886.
2. The Exhibition will be opened on 4th May, and will be closed on 30th October 1886.
3. Schedules of application for space may be had from the Secretary, Mr. James Marchbank, 29, Hanover street, Edinburgh. These must be filled up and returned on or before the 1st January 1886. The decision of the Space Committee will be notified as soon as possible after that date.
4. No goods will be received prior to 15th March 1886, without special permission, nor after 15th April 1886; but prior arrangements may be made for motors, boilers, or any exhibits requiring under-building.
5. The classification is not exhaustive. Where there does not appear to be any head under which an exhibit may be included, the exhibitors should apply for space, leaving the Executive Council to judge which group most nearly resembles the article he proposes to send.

6. Should any goods be delivered in the absence of the exhibitor, or his representative, the Executive Council will not be responsible for any loss or damage thereto arising from any cause whatever.

7. The Executive Council reserve the right to refuse any exhibit, without stating any reason for so doing.

8. Cases must be unpacked as soon as possible, and the empty cases removed from the ground at the expense and risk of the exhibitor; the Executive Council will endeavour to make arrangements for the storage of these at the expense of the exhibitor.

9. Charge will be made for space, except in special cases to be determined by the Executive Council. Exhibitors will have to pay all expenses of conveying, delivering, arranging, fixing, and removing their exhibits, and also the cost of the erection of all fixtures, screens, and counters when required; and they must personally, or by a representative, superintend the transmission, reception, unpacking, installation, and (at the close of the exhibition) the removal of their goods. The Executive Council reserve to themselves the right of doing whatever may be considered necessary at the expense of the exhibitor, unless this regulation is strictly complied with.

10. The Executive Council will endeavour to obtain, from the various railways and carriers, special terms for the conveyance to and from the exhibition; and should they succeed in doing so, such arrangements will be communicated to intending exhibitors.

11. All packages containing goods for Exhibition must have painted on them the distinctive mark (I E E) 1886 together with the name and address of the exhibitor.

Labels for this purpose will be supplied to each exhibitor.

12. Motive power (water, gas, and steam) will be supplied under certain conditions. Exhibitors requiring this must make special application to the Secretary, stating at what speed each machine is to be driven and power required. The furnishing of counter shafting will be at the expense of exhibitors. All steam-boilers must be placed under efficient inspection, which will be arranged by the Executive Council at the expense of exhibitors.

13. Passes to the exhibition will be granted to exhibitors and to their attendants. If it is found that they are transferred, they will be immediately cancelled.

14. No explosives or any substances which, in the judgment of the Executive, are dangerous will be admitted, but they may be represented by models.

15. Spirits, oils, essences, corrosive substances, or anything likely to injure other articles or cause inconvenience to the public, must be placed in strong and suitable vessels of small size.

16. The Executive Council reserve to themselves the right of examining, or testing, any of the exhibits. If any damage, or injury shall be occasioned during the exhibition by any exhibited machine, implement, or article, to any visitor or other person, then the exhibitor to whom such machinery, implement, or article may belong shall indemnify and hold harmless the said Council from and against all actions, suits, expenses, and claims on account or in respect of any such damage or injury which may be so caused.

17. While the Executive Council will not be responsible for loss or damage to any exhibit resulting from any cause whatever, they will nevertheless take every precaution for the care and preservation of the exhibits.

18. The Executive Council reserve the right to remove the exhibits of any one who does not conform to the regulations.

19. No article exhibited may be copied, photographed, drawn, or reproduced without the special permission of the exhibitor and of the Executive Council.

20. All cases, counters, platforms, screens, partitions must not (without special permission) exceed the following dimensions:—

Show cases and partitions	... 10 feet above the floor
Counters	... 2 feet 6 inches above the floor.
Platforms	... 1 foot above the floor.

21. Exhibitors may erect railings around their stands, and provide canopies, subject to approval: in every instance these railings must be within the area of the space allotted. In the case of machinery in motion, it is imperative that it be sufficiently railed.

22. Loan exhibits will be specially numbered and catalogued with the name of the sender. The Fine Art exhibits will be received under special regulations, which will be supplied on application to the Convener of the Sectional Committee.

23. The Artisan Exhibits will be specially numbered and catalogued with the name of the sender. These may be located in a distinct section, or otherwise, as the Executive Council may think proper.

24. The flooring must not be altered, removed, or strengthened except by sanction of the Executive Council.

25. No exhibitor will be permitted to display exhibits in such a manner as to obstruct the light, or impede the view along the open spaces, or to occasion inconvenience or injury to other exhibitors.

26. In order to ensure uniformity of decoration, no exhibitor will be allowed to put up flags, banners, or other kind of decoration without permission, and for covering counters, screens, or partitions, a material will be selected, which may be procured by exhibitors at the building.

27. Signs or name-boards must be placed to the satisfaction of the Space Committee, and must in no case interfere with the lighting. They must be black with gold letter.

28. All hand-bills, printed matter, &c., connected with exhibits, and intended for gratuitous distribution, must first receive the approval and permission of the Executive Council which permission may be withdrawn at any time.

29. Exhibitors will be required to provide all necessary attendance to keep their stands and exhibits properly cleaned and in good order during the whole period of the Exhibition.

30. No exhibitor will be allowed to transfer any portion of the space allotted to him, or to allow any other than his own exhibits to be placed thereon.

31. All goods must be exhibited in the name of the individual or firm signing the application form.

32. Exhibitors will be permitted to mark the selling prices of the various articles exhibited for the information of the juries and visitors.

33. Exhibitors or their attendants may explain their exhibits to visitors, but they will not be allowed to press visitors to purchase the goods, the Exhibition being intended primarily for purposes of display.

34. Diplomas for gold, silver, and bronze medals and honorable mention will be awarded to exhibitors on the recommendation of juries, to whom power will be given to make an adequate number of awards, as follows, viz. :—

- | | |
|-----|---------------------------|
| (1) | Diplomas for Gold Medals. |
| (2) | Do. Silver do. |
| (3) | Do. Bronze do. |
| (4) | Do. Honorable Mention. |

35. No exhibit can be removed before the close of the Exhibition, without the special permission of the Executive Council. Exhibits not removed within fifteen days after the close of the Exhibition will be warehoused at the cost and risk of the owners, and whatever remains after three months will be sold by auction, and the proceeds applied to defray expenses.

36. All who become exhibitors signify by so doing their compliance with the whole of these regulations, together with such other regulations as the Executive Council may issue from time to time.

37. The Executive Council reserve to themselves the sole right of compiling and printing a catalogue of exhibits.

38. Any exhibitor having cause to complain regarding the conduct of any official or attendant must give notice in writing to the Executive Council.

39. The Executive Council reserve the right to order the removal of any attendant whose behaviour they consider unseemly.

40. The right to alter, amend, add to, or cancel any of these rules is reserved by the Executive Council.

REGULATIONS RELATIVE TO "OLD EDINBURGH."

41. As this is regarded as a special feature of the Exhibition, parties applying for space must carefully indicate the corporation, guild, or craft they desire to represent.

42. In every instance the exhibitors will be required to arrange that their attendants shall wear the costumes of their respective periods and crafts. Designs will be furnished by the Executive Council, or exhibitors may submit these for approval.

43. In no instance will an exhibitor be permitted to introduce more than one craft into the space allotted to him.

44. Special care will be required by the Executive Council in cases where fire or gas is used in any portion of these premises, and a responsible officer will be appointed to carry out the injunctions of the Committee in this respect.

SPECIAL REGULATIONS AFFECTING FOREIGN EXHIBITS.

45. Applications for space from foreign countries will be received until 1st January 1886.

46. Applicants for space from foreign countries, where no Agent or Commissioner has been nominated, must appoint representatives to act on their behalf.

47. Agents or Commissioners must report to the Executive Committee the particulars of all exhibits proposed to be sent from their respective countries, and any proposed distribution of space allotted to these countries.

48. The letters **LEE** (in diamond) 1886 must be painted on all packages sent from abroad. The name of the country must also be put on, along with a distinctive private mark, which must be intimated to the Secretary by post.

CLASSIFICATION.

CLASS I.

MINERALS, MINING, QUARRYING, AND METALLURGY.

- Coal.
- Building and Paving Stones, Slate, Monumental Granite, &c.
- Limestone and Cements.
- Millstones and Whetstones.
- Iron, Lead, Copper, & other Ores.
- Pig Iron, Wrought iron, Steel—*In process of Manufacture or ready for use in the Arts.*
- Lead, Copper, Zinc, Tin, and Brass.
- Gold, Silver, Platinum, and other Metals.
- Machinery and Apparatus of all descriptions used in Mining, Quarrying, and Metallurgy, or Models thereof.

CLASS II.

POTTERY, GLASS, AND KINDRED INDUSTRIES.

- Brick and Tiles (Plain and Decorative).
- Earthenware and Stoneware.
- Porcelain.
- Glass of every description (Sheet, Plate, &c., Colored.)
- Stained Glass for Architectural Purposes, &c.
- Flint Glass or Crystal.
- Bottle and Slag Glass.

CLASS III.

CHEMISTRY, PHARMACY, AND FOOD.

- Acids—Sulphuric, Nitric, Hydrochloric.
- Alkalies—Soda, Potash, Magnesia, Lime Compounds.

- Finer Chemicals, including Coal-Tar Colors.
- Petroleum, Paraffin Oil, Paraffin Products.
- Pharmaceutical Products.
- Food (including Drinks).

CLASS IV.

ANIMAL AND VEGETABLE SUBSTANCES AND THEIR MANUFACTURE.

- Gums, Resins, Gutta Percha, India-Rubber, Vegetable Oils.
- Woods used in Construction.
- Dyeing and Tanning Materials.
- Textile Materials and Fabrics (Linen, Woollen, Jute, Cotton, Hemp), with Machinery employed for Spinning and Weaving. Sewing Machines, &c., in motion or otherwise.
- Leather, Shoe-making, &c.
- Costume.
- Ladies' Work—Embroidery, Art Needle-work, &c.
- Hat-making.

CLASS V.

PAPER MANUFACTURE, STATIONERY, PRINTING, AND BOOK-BINDING.

- Materials used, or which have been used, for Paper making.
- Paper of all kinds—Wrapping, Writing, Drawing, Printing, Mounting-Boards, Mill-Boards, &c.
- Papier-Mache.
- Manufactured Stationery.
- Type Printing.
- Lithographing and Engraving, &c.
- Book-binding.

CLASS VI.

PRIME MOVERS.

- Steam-Engines (Marine and Land), Gas, Electric, Hydraulic, Hot Air, &c.; Water-Wheels, Turbines, Steam Pumps, &c.
- Boilers, Smoke-Consuming Apparatus, &c.
- Accessories of Engines or Boilers.

CLASS VII.

MANUFACTURES IN METAL.

- Hardware, Edge-Tools, Cutlery, &c.
- Military and Sporting Arms; Weapons of various kinds.
- Powder, Britannia Metal, German Silver, and Nickel Wares.
- Exhibits of Articles made of Brass, Copper, Lead, or Zinc, not coming under the Class Engineering and Architecture.
- Gold and Silver Work and Jewellery.

CLASS VIII.

RAILWAY, TRAMWAY, AND VEHICULAR APPLIANCES.

- Rails, Switches, Signalling Apparatus.
- Locomotives, Goods Waggon, &c.
- Tramway Cars, Rails, Permanent Way, &c.
- Carriages, Vehicles, and Accessories, such as Brakes, Ticket-Checking Apparatus, &c.
- Bicycles, Triocycles.

CLASS IX.

CIVIL AND MILITARY ENGINEERING, BUILDING, CONSTRUCTION, SHIP-BUILDING.

- Models and Details of Bridges, Docks, Lighthouses, &c.
- Field Guns, Armour-Plate, Large Shot and Shell, &c.
- Models of Buildings and Parts of Buildings.
- Gates, Railings, Balconies, Beams, &c.
- Sanitary Appliances.
- Models of Ships, Ship Plates, Beams, &c.

CLASS X.

FURNITURE AND DECORATION.

- Wood Furniture.
- Marble Furniture.
- Metal Furniture.
- Basket Work—Bamboo, Willow, &c.
- Furniture of Mixed Construction.
- Paper-Hangings, Embossings, Linoleum and Floor Cloth, &c.
- Painted Wall Decoration.
- Stained Glass.
- Fancy Articles for House Decoration.

CLASS XI.

SCIENTIFIC APPLIANCES.

Models of Special Apparatus for Illuminating (electrically or otherwise), Heating, or for Motor Power, for Domestic purposes, such as Oil, Gas, Hot-Air and Electric Engines; Surgical, Medical, Mathematical, Meteorological, Astronomical, and Nautical or Military Adaptations of Scientific Inventions of novel application or design; Clocks, Watches, &c., in progress of manufacture, &c. Photographs, Drawings, or Illustrations of quaint design of any Instrument or Apparatus of Antiquarian interest in this section may be exhibited.

CLASS XII.

EDUCATIONAL APPLIANCES.

- Models, &c., adapted for illustrating Technical and Scientific School Teaching, &c.; Appliances and School Fittings with regard to utility and economy; Museum and Microscopic Preparations for use in Secondary Schools; Maps, Globes, Diagrams, Photographs, &c.
- Musical and Musical Instruments.

CLASS XIII.
SEA INDUSTRIES.

1. Fishing Boats.
2. Fishing Apparatus (Nets, Lines, Hooks, &c.)
3. Fish Hatching Apparatus, &c.
4. Fish Curing and Preserving.
5. Utilisation of Fish Oil, Sea-Weed, &c., including Isinglass, Kolp, Fish Glue, and Caviare, &c.

CLASS XIV.
FINE ARTS.

1. Oil Paintings.
2. Water Colour Drawings.

CLASS XV.

REPRODUCTIONS OF OLD BUILDINGS OR OLD STREETS,
OR PORTIONS OF THESE.

Exhibits under this class will be accommodated in "OLD EDINBURGH," a Full-sized Model of Street, illustrating exact *similes* of Luckenbooths, West Port, Lawnmarket, West Bow, and other Old Historical Buildings of Fourteenth, Fifteenth, and Sixteenth Centuries.

Note.—In the buildings of this, which may be looked upon as a special feature of the Exhibition, the various Tradesmen desiring space therein will be located under the distinctive Corporation or Guild of the period pertaining to their Crafts, and the attendants should wear the costumes of their respective Periods and Crafts.

The Industries proposed to be represented in "OLD EDINBURGH" will embrace Typefoundry, Printing, Engraving, Lithographing, and Photographing, Book-binding, Furniture, Carvings, House Decoration, Tapestry, Silver and Gold Plating, Jewellery, &c., or such other Handicrafts as the Committee may approve.

AGRICULTURAL DURBAR AT LUCKNOW.

[FROM AN OCCASIONAL CORRESPONDENT.]

LUCKNOW, December 7.

ON the afternoon of Thursday, the 3rd December, the first "Agricultural Durbar" known in these provinces was held by the Lieutenant-Governor and Chief Commissioner at his Honor's camp, behind Government House. If the ceremony was not as prolonged and imposing as is sometimes the case in darbars, the occasion was one of peculiar interest—sufficiently so at all events to justify me in sketching briefly for readers of the *Pioneer* its origin and history.

It appears then that during the past year the head of the Agricultural Department in these provinces (*viz.*, the Director of Agriculture and Commerce) started the idea—a novel and at first sight somewhat problematic one of associating with him, in the preparation of reliable monthly forecasts of wheat and other export crops, a body of selected zemindars and talukdars, over four hundred in number, and hailing from all parts of the N.W.P. and Oudh. Gradually the functions of these gentlemen were widened and extended. From being at the outset of the movement simply amateur crop reporters, they have become responsible referees in numerous important agricultural and economic questions; they have afforded much valuable assistance to the department to which they are, so to speak, affiliated; and they have been the means, unconsciously perhaps, but none the less successfully, of starting a mode of co-operation of the landed classes with the Agricultural Department the results of which are likely to prove extremely valuable. An attempt has been made in short to associate the people with the administration in the discussion and treatment of matters in which the people are themselves deeply and permanently interested.

The scheme thus started might or might not have borne much valuable fruit of itself, but it has undoubtedly received from the Agricultural Durbar, which was held by Sir Alfred Lyall on the 3rd of December, an impetus that practically ensures success. The Lieutenant-Governor was from the first interested in the matter; and it was at his express wish that the representatives of these volunteer agents of the Director of Agriculture and Commerce were invited to meet his Honor in public darbar—to be thanked for their labours in the past, encouraged to pursue them zealously in the future, and formed (along with the collaborators whom they represented) into an Agricultural Association of a practical and working kind, to which the Government might confidently look for information, advice, and assistance.

It was accordingly arranged that some sixty of the principal men (that is, those who had most interested themselves in the movement) should be invited by the Director—first, to be present at the opening of the Lucknow Exhibition, and, second, to have the honor of meeting the Lieutenant-Governor and Chief Commissioner in public darbar on December 3rd. By half-past 1 o'clock on the

afternoon in question the zemindars and talukdars were seated in the order of their position or rank in the darbar tent, and from that time till his Honor's appearance at 3 o'clock they were engaged, under the presidency of the Director and his assistants, in discussing the following topics:—

I.—Measures for initiating those connected with the land, both landlords and tenants, in such improved methods of tillage and agricultural management as might from time to time be established by successful experiments at the Cawnpore farm.

II.—Measures for popularizing the use of such agricultural implements, as similar experiments to those mentioned above had proved to be really useful improvements on the implements in common use.

III.—Measures for supplying cultivators with the best and purest seed for such valuable export crops as wheat, cotton, linseed, &c.

IV.—Measures for the organisation of an Agricultural Association for the United Provinces, with certain definite duties and responsibilities.

These subjects were discussed freely by all present. The principal speakers, as the records (access to which was courteously permitted us) show, were: for the N.W.P., the Raja of Haldour (Bijnor), Syed Mahrban Ali (Baludshuhur), Mahomed Yusuf Ali Khan (Aligarh), Chowdhri Dobi Singh (Meerut), Mahomed Ali Khan (Baludshuhur), and Mahabir Prasad Singh (Allahabad); and for Oudh, the Raja of Bhinga, Raja Jagmohan Singh, and Thakur Bhisunath Baksh Singh, all talukdars of position and influence, Pandit Ajadhya Pershad (Shahjehanpore), who has been appointed honorary Assistant Director, recorded the minutes and took a prominent part in the discussion.

Precisely at 3 o'clock the Lieutenant-Governor was received, at the entrance of the darbar tent, by Mr. Donald Smeaton, Director of Agriculture and Commerce, and Colonel Pitcher, Deputy Director, and Mir Mahomed Hyssain, Assistant Director, and conducted to the chair of state. His Honor was accompanied by his personal staff, and the following gentlemen among others were in attendance: Mr. Lawrence (Commissioner of Allahabad), Mr. Rivett Carnac, (Opium Agent), Mr. Mulock (Judge of Shahjehanpore), Mr. R. Smeaton (Financial Secretary). With the Lieutenant-Governor's permission, the Director proceeded to present the gentlemen one by one to his Honor, who touched and remitted the *nuzzers* which were offered, according to the old custom prevalent on such occasions. This ceremonial part of the business being over, Sir Alfred Lyall addressed the assembly in the vernacular. He thanked them cordially for the work which they had done, and pointed out the great advantage of accurate and punctual forecasts of the chief export crops in the interests of the commercial world, both in London and in India and of agriculture in these provinces. He regarded it as of great importance that the Government should be able to depend, with some confidence, on the landed classes for aid in obtaining really trustworthy information on agricultural matters, and hoped that the gentlemen present, and those whom they represented, would continue the voluntary labours which they had so well begun. His Honor alluded to the great need of developing to the utmost extent possible the agricultural resources of the United Provinces, and of endeavouring by every means to increase produce and cheapen production, and concluded by expressing a hope that at the next darbar of this kind which he proposed holding in the following year, there would be some substantial progress to be reported.

At Mr. Smeaton's request, Pandit Ajadhya Pershad, honorary Assistant Director, then briefly announced to his Honor the conclusions arrived at on the four topics which had that day been discussed. Regarding the first, it had been agreed that the landed proprietors of the N.W.P. and Oudh should from time to time depute selected cultivators either to the experimental station at Cawnpore or to the "demonstration" farms at Meerut and elsewhere for the purpose of being made practically acquainted with such measures and processes as had been proved to be advantageous and suitable, so as to be in a position on their return home to initiate their fellow-cultivators in these matters. It had further been resolved that an attempt should be made to start the teaching of elementary agricultural principles in village schools.

On the second topic it had been agreed that the plan lately adopted by the Director of sending out trained apprentices with the new ploughs on tour during the ploughing season (and with other implements at other times) in selected districts, should be extended, and that measures should be taken with this object in the ensuing autumn with the view of letting cultivators see the new plough at work side by side with the country plough in their fields, and of judging for themselves of the superiority of the former over the

latter in agricultural work. The gentlemen present had further willingly promised to do all in their power to spread among their people a sound practical knowledge of the working of these new implements, and of the advantages to be derived from their use. On the third point it had been decided that the present system should meanwhile be continued: the Government, through the Director of Agriculture and Commerce, selecting and distributing to all who desired it, the best class of seed procurable. It was admitted that this plan had worked very satisfactorily—in fact, the demand for the selected seed had far exceeded the supply owing to sudden and unforeseen requisitions from persons who had not at first contemplated applying. On the fourth and last point, the meeting had been unable to arrive at a complete agreement, and desired to reserve further discussion till the following day, when the gentlemen present were to meet in committee. But the general feeling was very strongly in favour of the immediate organisation of an Agricultural Association with branches for both Provinces, and perhaps sub-branches for some of the larger divisions.

Raja Jag Mohan Singh, on behalf of Oudh and the Raja of Haldour on the part of the N.-W. P., then advanced to the front, and thanked the Lieutenant-Governor for kindly consenting to meet them in durbar, assuring him of their genuine earnestness in co-operating with the Director and his staff, and promising that no pains would be spared by them in rendering this co-operation productive of real benefit to the agricultural classes and interests in the provinces.

This closed the interesting proceedings, and the durbar was formally dismissed. The movement could not possibly have had a more auspicious commencement. It is noteworthy that the zemindars and talukdars who form the (Inchoate) Association have already rendered valuable aid to the Agricultural Bureau by their early and accurate statistics regarding the chief export crops. The durbar to which they were invited marked, therefore, an epoch of good work actually done, not the mere opening of an Association from which results were to be hoped. As such, the occasion was both an interesting and important one, well meriting this brief notice of its proceedings in the columns of the *Pioneer*.—*Pioneer*.

SILAGE STACKING.

We have received from Mr. James Hunt, of Brentry Farm, Westbury-on-Trym, near Bristol, a copy of his pamphlet on the above subject; and as silos and ensilage are just now very much before the public, have been the subject of investigation by a Parliamentary Commission, and those who take an interest in the matter have formed themselves into an Ensilage Society, we deem it advisable to bring the points thus published before the notice of our readers. The great drawback hitherto to ordinary farmers adopting the system as part of their farm practice—or even trying it as an experiment—is the initial and heavy expense incurred in the erection of silos, even of those on the simplest and cheapest plan.

Mr. Hunt proposes to do away with silos altogether, and simply build up the green grass as an ordinary hay stack anywhere, but in the corner of the field where it grew by preference, so as to save excessive carting as much as possible. There is, of course, nothing novel about the mere stacking of silage—as that has been tried again and again—but it is in the application of the pressure that Mr. Hunt claims supremacy. Next to erecting a silo, the application of the pressure has been a great bugbear. Pressure by weights may now be said to be superseded by mechanical arrangements of some kind, and the author claims to have invented a cheap and efficient means of pressing ordinary stacks.

Briefly, the method is as follows:—Rough beams of wood, iron rails, or anything of that kind, are laid down at intervals apart on the site of the proposed stack; the stack is then built up like an ordinary haystack—sloping roof and all; poles or bars of any kind are laid lengthways along the top; chains are then fastened to the ends of the poles underneath, and passed over the top; and by attaching a particular kind of lever, on the end of which there is an arrangement of sliding bars of iron, with holes at regular intervals and self-acting spring hooks, the ends of the chains can be levered down link by link, as easily as a man will press a bale of hay in a handbaling machine. The ends of the chains can then be made fast, and the lever detached to be used on the next set.

Mr. Hunt has not been long in finding out that a great drawback to stacking silage in the open was the loss from the sides going mouldy, and he states he was the first to discover that common salt could counteract this, as also a composition, of which he does not give the ingredients. We, however, differ very decidedly as to the quantity of salt to be employed. Mr. Hunt states that about

2 lbs. per cwt. should be applied. Now, as an animal of the cattle kind only requires some 4oz. daily, it is plain that in consuming 56 lbs. of ensilage a beast will take in four times as much salt as it requires. This fact was first pointed out some four years ago in our columns by Professor Wallace. We would advise that this large quantity be applied to the outside layers only, where it will do most good. In feeding, this portion can be mixed with the rest.

In short, Mr. Hunt offers the gears and levers necessary to press a stack of 60 tons (but not including the chains) for £3.15s. and brings evidence to show that salt will keep the outside good. Sweet silage can be quite well made on Mr. Fry's system, by simply building the stack up piece by piece, and allowing the heat to rise above 120 degs. before putting on pressure. The relative cost of hay and silage making have been often worked out, but as many people believe that silage will take the place of roots and cut of hay, the fact that five times more weight has to be carted home than is the case with hay, will not deter farmers from trying it. We have no hesitation in saying that stacking silage has been wonderfully successful in the past, and promises to be completely so in the future, and will therefore commend itself to farmers more and more. We recommend a perusal of this pamphlet to all concerned in ensilage.—*North British Agriculturist*.

OUR MINERAL WEALTH.

Few persons who have not had their attention specially called to the subject have any conception of the vastness of our mineral wealth, nor the amount it annually contributes to the sum total of the products of the country. Its contributions may be classed as metals, coal, petroleum, building stone, brick, and other products of clay, lime, cement, phosphates, salt, natural gas, and chemical substances used in the arts. From the report of the geological survey for 1884, just published, we condense the following facts and figures, showing the value of the output from all these sources in 1884:—

The total value of coal mined was, of anthracite, \$65,351,512, of bituminous and all other coals, \$77,417,066, a total of \$143,768,578. The product of Noproloam amounted to 24,039,758 barrels of 42 gallons each, which, at an average price of 85 cents per barrel, was worth \$20,476,294. The estimated value of natural gas used was \$1,460,000. The total value of iron and steel in the first stages of manufacture amounted to \$107,000,009. Of precious metals, the product of gold from the mines was \$30,800,000, and of silver, \$15,800,000, a total of \$79,600,000. Our total copper product, at an average price of 12½ cents per pound, amounted to \$17,789,637. Lead footed up \$10,537,042, and zinc \$3,422,708. Quicksilver amounted to \$936,327. The total estimated value of building stone quarried during the year was \$19,000,000, and of brick and tile made, \$30,000,000. Lime figures at \$18,500,000, and cement at \$210,000. The South Carolina phosphate rock quarried during the year is placed at \$2,374,784. Salt figures at \$4,197,734, and bromine, borax, alum, copperas and mineral waters together make a total of \$2,935,554, making a grand total of \$462,208,704. This is a large amount to add substantially (as the most of it is added) to the wealth of the country from the bowels of the earth. But when it is taken into account that a very large percentage of this total value represents wages paid to laborers, it gives an added significance to the subject, affording as it does employment and support to a vast labouring population dependent upon the farmer for the food they eat and upon the manufacturing and mercantile interests for the supply of their other wants. It is safe to assume that fully three-fourths of the above grand total represents labour in some form. This is equivalent to a sum of \$346,656,528. Allowing an average of \$2.00 per day paid for labor for 300 days in the year this sum represents the employment of 57,776 labourers, and taking into account the families dependent upon them it represents the support of a population of not less than 200,000 persons. But these values as above stated represents only the values of these products in their crude state; as they enter into manufacture, or are moved to market they furnish employment to a still larger army of workers, by whose labour their value is greatly augmented. Taking into account our facilities for production from the farm, our wealth in mines and forests, our natural and artificial means of transportation, and our widely diversified industries, this country should have little to complain of if we make a wise use of natural advantages.—*Farmers' Review*.

DON'T DIE IN THE HOUSE.

"Rough on Rats" clears out rats, mice, beetles, roaches, bed-bugs, flies, ants, insects, moles, chipmunks, gophers.

A. W. Mason & Co., Calcutta, Sole Agents.

THE ENSILAGE PROCESS.

THE *Times* says the evidence taken by the Private Ensilage Commission and the preliminary report based upon it have put beyond all doubt the value of the ensilage process as an auxiliary to farm practice. The commissioners were willing to give a hearing to all witnesses, to the opponents of ensilage no less than its friends and advocates. But in whatever quarter they applied, they heard no expression of any decidedly unfavourable views. The ideal silo, as described by one of the scientific witnesses, is simply a closed chamber from which atmospheric air is excluded, the airspace within it being filled with some neutral such as carbonic acid gas. This admits of being realised with more or less approach to perfection in a great variety of ways. There is no definition of the material from which the walls of the silo are to be made, and we find accordingly all sorts of material employed. Bricks, stones, slabs of clay, iron, wood, sometimes coated internally with cement, sometimes uncoated—there were advocates for every one of them. Then as to the food contents of the silo, there was nothing excluded which cattle could be induced to eat, and a good deal put in which was not fit to be eaten until it had been subjected to the process of fermentation which went on inside the silo. The stalks of maize are naturally an indigestible food, but they improve under fermentation. The chief thing necessary with almost all green food in order to insure good results seems to be that it shall be cut before it is fully ripe. Grass must be cut before it seeds; maize before the ears are developed, and before the stalk is fully hardened. The mixed mass of green stuff from which the ensilage is to come is found to shrink in bulk very considerably. The general method is to put it in by degrees, and to tread or press down each day's addition so as to fill the silo to the top and to reduce the shrinkage to a minimum. The result aimed at is simple enough. The mode of attaining it, as described to the Commissioners, was different in almost every instance. Various forms of elaborate machinery for compression were in favour with some of the witnesses. Others were content with putting earth or bricks at the top of the silo. One ingenious person used old petroleum casks filled with water up to the point which gave them the desired weight. Closely connected with this part of the subject is the roofing of the silo, and here again comes a fresh sub-division of method. That the silo must be made thoroughly air-tight was allowed on all hands. That it must be well filled was the opinion of every witness but one, who was satisfied with having his silo air-tight, since it was only by the intrusion of atmospheric air that any harm could come to the contents. On the question of cost there was a marked difference between one method and another as on most other points. One form of silo was shown to be capable of construction at 7s. 6d. per ton of inside space. For another form the cost rose to 30s. In many instances it was found impossible to give an estimate of cost. Sometimes no distinct account had been kept. Frequently, too, some old material had been taken as it stood and put to new use as a silo. The whole system is clearly in the experimental stage. The adverse claims of efficiency and economy have not yet been reconciled. Some of the witnesses, indeed, who went to work on the least expensive plan, declared themselves satisfied that it was as good as any other, and that no advantage could be gained, worth speaking of, by any increase of cost. On the cheapest of all the methods of producing ensilage—that of stacking the fodder and doing without a silo in any form—the commissioners have not been able to pronounce favourably as yet. The system has been tried on Lord Crawford's estate, and a practical witness considers the results as equivalent to so much dung. Mr. R. J. Wilberforce has made an unintended experiment in the same direction, and one which he has no wish to repeat. He was trying to stack hay green, and to dry it by an exhaust-fan. This he so entirely failed to do that he gave up the stack as so much waste stuff. But when he came to cut it down he found the outside waste to a depth of about three feet, the next layer fairly good food, and the centre sweet ensilage. On the advantages of the ensilage system the variations of opinion are in degrees rather than in kind. We may claim for it, as admitted, that it gives the means of supplying cattle with green food of excellent quality at all times of the year, and that in a climate like our own it enables food to be preserved with certainty, which would be liable to be wasted otherwise. The ensilage system has been so lately introduced into this country, that there has been no time as yet for its practitioners to come to an agreement about it. It has established itself so firmly, and has gained ground so rapidly, as to prove its value in the opinion of those who have given it a trial, or who have been witnesses of their neighbours' success and have begun to experiment for themselves.—*North British Agriculturist*.

PROFESSOR SHELDON ON DAIRY FARMING.

ADDRESSING a large assemblage at the Working Dairy in connection with the recent Dairy Show in London, Professor Sheldon referred to the origin, present position, and prospects of the British Dairy Association. He stated that until the present year, the association had not progressed very satisfactorily, but this year the number of members had largely increased, and he believed that they would be able to accomplish that which they desired in respect to dairy education. Although the holding of shows was an important feature, that was not the chief object of the association, which was to improve the dairy husbandry of the country. The shows were supposed to express the highest attainment to which they could get, and there were to be found both butter and cheese, the very best of their kind. Their object was not to get together a large quantity of these things—which, no doubt, was very useful for supplying data from which to draw comparisons—

but to provide examples for imitation. The shows were intended to be, and were regarded as, the results of work done. The association desired to educate persons in dairy processes of husbandry in all the different branches. The present condition of dairy husbandry was very unsatisfactory. The depression throughout England in all the arable districts had at last overtaken dairy farming, and it was to the credit of dairy farming that it had held out so long. Having been the last to succumb to the depression, he believed it had sufficient vitality to be one of the first industries to recover therefrom. There were in this year's show some most magnificent samples of cheese, the show being the very best of those he had attended in the building. The exhibits of both butter and cheese this week were the best he had seen at this association's shows. It was his opinion that they ought to establish a number of dairy schools, for there was a great want of them in England. In Ireland such schools had been founded by private munificence, and there were now several in the south of that country. An important one was that known as the Munster Dairy School, near the town of Cork. The effect of that upon the butter-making of Ireland had been very marked indeed. He had it upon the highest authority that the result of the training at that school had been to raise the average value of butter in that part of Ireland from something like 1d. to 2d. per lb. A result like that was certainly worth striving for; and if such a result could be achieved in a few years, what might not be obtained after the institution had been working for twenty or thirty years? He had noted in many instances as a judge of dairy produce, especially as to the qualities of butter, and it afforded him the greatest pleasure to bear his testimony to the marked skill which dairymaids had displayed in the art of butter-making. He had never seen in any part of the country a higher degree of skill displayed by any butter-makers than that which was displayed by the Irish girls at this show. But he was glad to say that Miss Holmes, of the Surridge Farm at Bromley, who was at the present show, had taken part in nearly every one of the competitions at Dublin. In England, schools were required not only for butter-making, but for cheese-making. There was great disparity shown in the quality of both cheese and butter in this country from milk presumably of about the same quality. There were found very varying degrees in both butter and cheese. At the Nantwich Cheese Factory cheese was produced which sold from 20s. to 68s. per cwt., and a disparity like that was absurd. What could be looked for in cheese which was sold for not more than 20s. per cwt.? The difference between that sum and 68s. made all the difference between ruin and prosperity. It seemed to him to be a pitiful thing that at the end of the nineteenth century their dairy education should have advanced so slowly, and should be so imperfect as to admit of such a disparity as 20s. to 68s. per cwt. for cheese. He noticed also, with regard to the butter markets in Ireland, last week the prices ranged from 60s. to 115s. per cwt.—a difference of close upon 100 per cent. In reply to one of the assembly, who asked the cause of that great difference, the Professor said that it was chiefly due to the want of method. Greater pains should be taken to improve the products from the milk of the cow. It was a matter of pain to him personally (having been engaged in dairy education for many years) to notice what a marked disparity there was in the quality of cheese and butter. The milk was just about the same everywhere, and any variation in butter or cheese made from it should not be in the quality but in the quantity produced. It should be tolerably uniform in quality. He felt convinced that there was a great future for dairy farming in this country. Whilst corn-growing was doomed in England, the consumption of fresh milk was increasing. It had trebled within the last twenty years in London, but still it was even now at a low ebb. Both cheese and butter ought to be consumed in much greater quantities, for there was no article of food so cheap as cheese. There was room for a great extension in the consumption of those commodities, and he hoped that that increase would be facilitated by the law enforcing the sale of pure milk and restricting the sale of artificial butter and prohibiting its being sold as genuine butter—(a voice, 'That's Protection'). No; it was prevention of adulteration. The persons who sold artificial butter as such under its proper designation were doing that which was right and proper, and beneficial to the poor; but when they tried to sell it as genuine butter they were attempting a fraud upon the public, and the public should be protected.

A gentleman amongst the audience said that in his county (Lancashire) butter was produced at soap factories, so he thought that more protection was needed.

Professor Sheldon agreed that the public needed protection in that matter, for there was no law which at present dealt sufficiently with butter adulteration. The adulteration laws were not sufficiently effective, and the dairy farmers had a just claim to be protected against a spurious article being sold as butter. Hutterine he did not object to in the least, but let it be made and sold as such. After some further general remarks about the show, the Professor concluded his interesting address.—*North British Agriculturist*.

HOLLOWAY'S OINTMENT AND PILL.—Old Sores, Wounds, and Ulcers.—The readiness with which Holloway's unguent removes all obstructions in the circulation of the vessels and lymphatic explains their irresistible influence in healing old sores, bad wounds, and indolent ulcers. To insure the desired effect the skin surrounding the diseased part should be fomented, dried, and immediately well rubbed with the Ointment. This will give purity to the foul blood, and strength to the weakened nerves, the only conditions necessary for the cure of all those ulcerations, which render life almost intolerable. No sooner is this Ointment's protective power exerted than the destructive process ceases, and the constructive business begins—new, healthy growth appears to fill up the lately painful excavated pit.

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucus gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty, brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after expending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

St. Mary-street, Peterborough, Nov. 29, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

Hensingham, Whitehaven, Oct. 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatobury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WEBB,

Chemist, Calne.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed) VINCENT A. WILLS,

Chemist-Dentist,

Merthyr Tydvil.

Preston, Sept. 21st, 1883.

To Mr. A. J. WHITE.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said, "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.—I am, dear Sir, yours faithfully,

(Signed)

W. BOWKER.

To A. J. WHITE, Esq.

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A
WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DEBILITY, ATTENUATION OF BODY, ERUPTIONS, LASSITUDE, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the sequelæ of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of *Wilkinson's Sarsaparilla*, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your *Essence of Red Jamaica Sarsaparilla* cured me of a Torpid Liver; all other remedies failed."—*Earl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Cocoa, Cinnamon, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at Observer Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the *T. A.*, as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1½.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for £1 10s. (or Rs. 18), carriage prepaid.

As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, DECEMBER 19, 1885.

[No. 51]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 9TH DECEMBER 1885.]

Madras.—General prospects fair; continue favourable in Bellary and Anantapore.

Bombay.—River falling in Sind. More rain wanted for rabi crops in parts of Nasik, Ahmednugger, Sholapore, and Khandesh. Standing crops suffering from drought in one taluka of Nasik and parts of Ahmednugger and from blight in parts of Bijapore. Reaping of *kharij* and sowing of rabi crops in progress in parts of seven districts. Cholera in parts of seven, fever in parts of sixteen, cattle-disease in parts of ten, and small-pox in parts of three districts.

Bengal.—No rain during the week. Rice harvest is proceeding, and is generally yielding a good outturn. Rabi crops everywhere, and poppy in Behar and Hazareebagh, are promising, but want rain in parts of Behar. Price of rice remained stationary in almost all districts during the week. Public health continues generally fair.

N. W. P. and Oudh.—Weather turning colder. Rain is needed in some districts for the rabi. Markets are well supplied and prices fairly steady. Public health is generally good.

Punjab.—No rain; it is much wanted. Cholera in parts of the Dera Ismail Khan district, elsewhere health is generally good. Rabi sowings nearly completed. Prices show a rising tendency.

Central Provinces.—Weather rather cloudy and less cold. *Kharij* harvest progressing; rabi sowings almost finished. Prospects favourable. Fever and cattle-disease in places. Prices steady.

British Burmah (December 2nd).—Slight cholera in eight districts, elsewhere public health good; cattle disease severe in one district, slight in five districts, elsewhere health of cattle good. Crop prospects good in all districts, except in Tharrawaddy and Prome, where the rainfall has not been sufficient. There has been heavy rain over the whole province and a violent gale on the seaboard; the extent of damage which the rain and the gale may have done to the crops is not yet known. (December 9th).—Slight cholera in seven districts, elsewhere public health good; slight cattle-disease in six districts, elsewhere health of cattle good. Crop prospects good in all districts except in Thayetmyo, where the crops are poor, and in Prome and Tharrawady, where they are fair.

Assam.—Weather seasonable. Public health fair. *Kalajar* seems still prevalent in parts of the Luki tahsil. Prospects of all crops good. Reaping of *sali* being continued. Cattle-disease again reported from some mouzabs. A few cases of cholera reported from Sunamgunj. Common rice 16 seers per rupee; tea season nearly closed.

Mysore and Coorg.—Public health generally good, except in parts where fever prevails; cattle-disease in parts of Shimogra, Kolar, and Kadur. Standing crops in good condition; crops sown late need rain; harvesting of *ragi* and of paddy in progress. Prices fluctuating.

Benar and Hyderabad.—Weather clear and cool. Cotton picking continues; *kharij* being cut, rabi prospects good. Wheat 22 and *jowari* 26 seers per rupee in Amraoti; *adi* crops prospering. Fever continues to prevail. Prices—white rice 14½, coarse rice 12½, white *juar* 20½, yellow *juar* 27, and tur 15½ seers per current sicca rupee in Hyderabad.

Central India States.—Price of wheat risen in Indore, stationary elsewhere. Health and prospects good. Weather seasonable; cholera still in Rewah. Rabi doing well; opium prospects good.

Rajpootana.—General health good, but fever to some extent still prevails. Weather clear and colder. Winter crops nearly all sown. Tanks and wells full everywhere except in Partabghur and Maywar. *Kharij* crop being gathered and the rabi thriving. Small-pox slightly prevalent in Maywar. Opium sowings commenced in Harawal. Prices stationary in some places and fluctuating in others. Cattle-disease prevalent in two tahsils.

Editorial Notes.

We learn that the Bombay cotton crop is proving an unusually early one, about 16,000 bales having already reached the market. The crop is expected to be one of the best, both in quantity and quality, ever known on the Bombay side of India. Estimates of the next six months' shipments range from one to one-and-a-quarter million bales.

.

THE first report of the Royal Commission on Trade has been issued, and shows that considerable depression has existed for the last five years as compared with the previous five years, but there is a marked difference of opinion as to possible remedies. The Birmingham Chamber of Commerce attributes the depression in part to German and Belgian competition, to foreign import duties on home-manufactured goods exported abroad, and to the exorbitant railway rates.

.

AMONG our selections this week will be found two very interesting papers—one on dairy farming on the continent, and the other on parasites affecting animals. The importance of the latter will be appreciated by agriculturists and farmers in this country, where very little attention is paid to a subject so vitally affecting meat consumers. Mr. Connachie has dealt very ably with the matter in hand, and we hope our professors in veterinary and agricultural colleges will take an opportunity of initiating the delivery of lectures of a similar character to the students entrusted to their care.

.

WE understand that a scheme for establishing an agricultural farm in connection with the Bombay Eurasian and Anglo-Indian Association has been drawn up and ordered to be circulated to the members of the council. A new branch of the Association has been formed at Dharwar. The newspaper proposed to be started as the organ of the Association, in the same way that the *Eastern Guardian* is the organ of the Madras Eurasian and Anglo-Indian Association, is proposed to be called the *Anglo-Indian Mail*.

.

THE latest published list of tea gardens or tea estates in Ceylon shows that there are at present 583 gardens, either bearing or under cultivation. But what strikes us as curious, when compared with the size and extent of Indian tea estates and gardens, is the small areas covered by most of the gardens individually. We notice that there is only one which covers 500 acres, while the greater number of the others do not exceed 100 acres in extent. This is of course not surprising when the area of the whole island is compared with the tea-growing districts of India.

.

Kuhlou's Trade Journal, in noticing the subject of tobacco cultivation in Germany, says :—

Official returns show that this year 19,579·2 hectares of land were cultivated with tobacco within the jurisdiction of the German customs authorities, against 21,090·6 hect. last year, a decrease of 1,511·4 hect. The falling-off applies almost entirely to Bavaria, Baden, Wurtemberg, Hesse, and Alsace-Lorraine, while there is an increase in the land thus cultivated in Pomerania, Brandenburg, Hanover, the province of Saxony, and Silesia. In the Kingdom of Prussia 661·5 hect. more are being cultivated with tobacco than in 1884.

BORING for petroleum in the Bolan, says a contemporary, may now be considered as past the experimental stage. The Canadian experts engaged, who have hitherto been cautious in expressing their opinion, are now confident that sufficient oil can be raised, not only to supply fuel for the railways near, but also for the lighting of all northern India. Some of the engines of the Pishin Railway are being altered so as to burn petroleum instead of wood; and the new fuel will, no doubt, in time be universal on that and the present Indus Valley line. Refining works, for the manufacture of lighting and lubricating oil, will follow; and in the course of a few years, American kerosine should be unknown in our bazaars.

**

TIMBER rot is looked upon as something which must be expected; but after a perusal of our paper on the "Impregnation of Timber," we hope our readers will have found something wherewith to keep off the dreaded rot. In this connection, the *Builder* says that nine-tenths of the decay of timber is due to rot occasioned by the common wood fungus. This parasite develops under two conditions, namely, moisture and heat, and both are present in new green or unseasoned timber employed in buildings. In old or seasoned timber, the former is wanting, and hence greater durability. If moisture only is present without heat, the fungus will not grow; if heat without moisture, it equally has no scope for development, and hence the protecting influence of ventilation.

**

WE learn from a home contemporary that the esparto grass trade in Tunis is now carried on there on a large scale, and large tracts of esparto-producing fields have been bought by speculators. The Anglo-French Esparto Fibre Company are developing their trade at Abouheduna, and a tramway is now being laid down by the same to carry the esparto fibre to the coast. But export duty is very heavy on this article, and competition by Tripoli and Algeria, where esparto pays no export duty, is telling much on the trade. This trade is said to be amongst the very foremost resources of the Lousa district. "Through good and bad, dry or rainy years, there is always a crop of it. The Arabs fall back on it chiefly in times of scarcity, when successive years have brought them deficient crops. But the duty on this article, especially at Lousa, is so heavy as to deter the Arabs from pulling and bringing it to the market, except when they feel the pinch of poverty."

**

THE Collector of the Nilgherries the other day submitted for orders the question, whether lands under coffee held on putta should be exempted from assessment for more than two years, as it had been the practice to exempt such lands for the first three years in other districts. At the same time, he took occasion to ask also whether it is the intention of Government that coffee land alone, and not tea, cinchona, &c., should be treated with indulgence. With regard to the first question, it has been decided not to take any further action as to what has been done in the past; but that no sufficient reason exists for departing from the rule laid down in 1860, so far as the future is concerned. As to the second point, it seems that when this question was raised, in connection with lands taken up under the Waste Land Rules, the Government directed that the concession made to tea lands should apply to such special products as coffee and cinchona, and not to tea only, and to grass land as well as forest. Therefore, reasoning from analogy, it has been decided that the indulgence extends to other special products also, and is not confined to coffee.

**

THE report on the state of the season and prospects of the crops, for the week ending 9th December 1885 is as follows:—

Heavy rain has fallen in British Birmah and slight rain in parts of the Madras Presidency, Mysore, and Coorg. Elsewhere the week has been rainless. Agricultural prospects continue fair in the Madras Presidency, though in one or two places some injury has been caused by insect, and in parts of Coimbatore more rain would be beneficial. In Mysore the standing crops are in good condition, but those sown late need rain. The *ragi* and paddy harvests are in progress. In Coorg the season promises well. In the Bombay Presidency *khari* crops are still being harvested and *rabi* sown. In

parts of Nasik, Ahmednugger, Sholapore, and Nasik, more rain is wanted for the latter. In the Berars, Hyderabad, and Central India and Rajpootana, the cutting of the *khari* crops is ~~in~~ progress, and the *rabi* crops promise well. The *rabi* sowings have been almost completed in the Central Provinces and in the Punjab. In the latter province rain is much wanted in several districts. In the North-Western Provinces and Oudh the *rabi* crops are coming up well, but more rain is wanted in the districts of Allahabad, Banda, Kumaon, and Jhansi. The rice harvest in Bengal is yielding a good outturn, and the *rabi* crops promise well. In Assam the state and prospects of the crops continue favourable. In British Burmah crop prospects are generally good in all districts except in Thayetmyo. The public health is fair in all provinces. Prices are generally steady everywhere except in the Punjab and Coorg where they show a tendency to rise, and in Mysore where they are fluctuating.

**

AN entomological lecture was delivered the other evening at the Indian Club by a Mr. P. Mowis, a foreigner, who has been devoting some of his leisure moments to the collection of butterflies, and especially those species which produce the silk-worm. The lecturer expounded some of the mysteries of the butterfly and insect creation, illustrating his experiences in the Himalaya and other regions in India, where he underwent the utmost privation in his researches into entomology. He exhibited fifty cases of butterflies, beetles, and other insects. He explained the different varieties of butterflies, their properties, and their natural uses, stating that his collection was chiefly from Darjeeling. The beetles, he added, were collected from Sikhim, and excelled in a great measure those obtained from Brazil. In describing the production of silk by silk-worms, he asserted that to manufacture 18 yards of silk, no less than 10,000 silk worms would have to be absorbed, and the time taken would be a twelve-month. He then showed the process by which the silk was manufactured from cocoons. On the subject of caterpillars he stated that there were five large families, and each caterpillar could consume ten times its own weight in a day. The cocoons he said were known to be eaten by the natives, who implicitly rely upon their efficacy for the prevention of fever. In the same way moths were eaten by natives as a specific for fever, and for other disorders. It was only recently that the marvellous faculty of providing silks for the covering of moth's eggs for protection was discovered. The silk was found in the pocket of a moth's wing. The lecture concluded with a general illustration of the utility of insect life in connection with human industries.

**

THE following summary of the German home trade for the week ending 18th November 1885, is taken from *Kuhlows*:—

The state of trade is about the same as last week: no appreciable change has set in during the last seven days. The good time is no doubt coming, but it is very long about it. After the prolonged period of ever-deepening depression which we have experienced, it is, however, a source of consolation that matters are not getting worse. The Iron trade continues very dull, especially the pig iron branch, the production of which, however, has not materially fallen off. Less is being produced in the rolled iron department, and little fear is entertained of any serious glut resulting. The coal market is satisfactorily situated, as it has now been for some weeks, nor is there any reason to suppose that a reaction will speedily set in. The iron and coal industries of Westphalia have of late been cheered by the prospect of the long-talked-of North Baltic Sea Canal being taken in hand with a determination to carry it through. Of course, such a gigantic work will require a long time for its completion, but the advantage of connecting the North and Baltic Seas by a ship canal, would undoubtedly be very considerable for the industries of the westernmost parts of the Empire. The Sugar market has been stronger during the week, though no great change in the situation can be reported. The offers of raw sugar have only been moderate—corresponding, in fact, to the requirements of refiners—so that the prices of high-polarising qualities were well maintained. A better business has been done in export sugar, and in consequence of hopeful reports from abroad a small advance of prices was secured. The tendency of the refined sugar market has been quiet. The unsatisfactory relation between the prices of raw and refined sugar, gives rise to the expectation that an

improvement will soon take place in regard to the latter, as a stronger demand is confidently relied on.

.*.*

THE *Corn* market is still dull. Wheat is flat, both native and Russian, and barley is the same, while little different can be said of rye. *Wool* sales have been confined within narrow limits, present necessities alone being covered, while prices are the same as before. *Cotton* has experienced a better trade during the week. The *Yarn* market is, generally speaking, dull, but there are exceptions. Soft worsted yarns are in good demand, and carded stuffs are better situated. On the whole the spinning industry is only fairly busy. Rough carded yarns go badly at present, but loop yarns are as taking as ever, though how long the fashion will continue is a difficult point to speculate upon. Manufacturers would perhaps do well not to build too many hopes on loops. The business in *Silk* goods has been improved by the low prices. In the *Leather* industry foreign trade has been good, but provincial buyers still continue reserved and only purchase what is really necessary. Favourable reports from producing countries have given a stimulus to the *Tobacco* market, and in some kinds the business has been considerably better. A further decline in prices has characterised the *Spirit* market. In most branches of industry a feeling of uncertainty has been caused by the declaration of war between Serbia and Bulgaria, for it is not possible to say to what developments the untoward incident may lead.

.*.*

DR. E. BONAVIA of Etawah has been endeavouring to arouse public attention to the value of lemon and lime juices in the treatment of malarious and other fevers. It is interesting to note that this mode of treatment for malarious fever has also attracted a great deal of attention in America, for we find the following remarks on this subject in a recent issue of the *N. Y. News* :—

The newest remedy for malaria is advertised in the drug stores as the Roman cure. It is described as the discovery of a physician in the miasmatic old city of the Caesars and the Pontiffs, where malaria is included with every lodging without extra charge in the bill. It consists simply of lemons cut up, peel and all, and boiled, the juice being taken cold on an empty stomach. The pharmacists claim that it has cured cases so stubborn, that quinine had no more effect on them than sugar or salt. The method of preparation is so simple that any one can make an experiment who chooses. The lemon must be cut up in small pieces, rind and pulp, each good-sized lemon being allowed a pint of water. When the water has boiled down to half a pint the medicine is done. It must then be strained through a cloth and put by to cool. It is sour enough to give a marble bust a wry face. The dose is from a teaspoonful to a table spoonful according to the staying powers of the patient's stomach, taken one hour before meals. Like the hot-water cure, wonderful stories are commencing to float around about the lemon cure, and it bids fair to become very popular. A physician who is a member of, and has many patients in, the New York Athletic Club, informed the *News* reporter that he had been giving concentrated lemon in malaria cases for nearly a year, and now scarcely ever uses quinine. The new remedy does all the work of quinine without affecting the nerves or the head as quinine certainly does.

.*.*

We offered some remarks a short time back on the effects of tea-drinking. The following practical hints by *Wong Chin Foo* (whoever he may be) in the *Cook*, should be read in connection with our paper :—

Use a China or porcelain pot. If you do use metal, let it be tin new, bright and clean; never use it when the tin is worn out and the iron is exposed. If you do, you are playing chemist and forming carbonate or tea-ate of iron. Use black tea. Green tea, when good, is kept at home. What goes abroad is bad, very bad and horrible. Besides containing the 203 adulterations the Chinese philanthropist puts up for the outside barbarian, it is always pervaded by copper dust from the dirty curling pans of the growers. Infuse your tea. Don't boil it. Place one teaspoonful of tea in the pot and pour over it one and a half cups of boiling water—that is, water really boiling. If your tea is poor, use more. It is cheaper though to buy good tea at the outset. Put your pot on the back part of the stove, carefully covered, so that it shall not lose its heat and the tea its bouquet. Let it remain

there five minutes; then drink it. Drink your tea plain. Don't add milk nor sugar. Tea brokers and tea-tasters never do; epicures never do; the Chinese never do. Milk contains fibrin, albumen or some other such stuff, and the tea a delicate amount of tannin. Mixing the two makes the liquid turbid. This turbidity, if I remember the encyclopædia aright, is tannate of fibrin, or leather. People who put milk in tea are, therefore, drinking boots and shoes in mild disguise.

A CORRESPONDENT of the *Gardener's Chronicle* writes as follows on the manurial value of freshly fallen leaves :—

Our knowledge regarding the manurial value of fallen leaves has recently been added to by Professor Emmerling and others, in a communication contributed to the current number of the *Bied. Centr.*, 1885. The results are given in the following tables :—

PERCENTAGE COMPOSITION.

	Grey Poplar (Folia salicifolia)	White Willow (Salix alba)	Silver Poplar (Populus alba)	Silver Birch (Betula pubescens)	Sycamore (A. racemosa)	Common Alder (Alnus glutinosa)	Oak (Quercus robur)	Beech (Fagus sylvatica)	Hornbeam (Carpinus betulus)
Water...	20.58	20.27	18.81	15.71	17.74	17.06	17.73	15.93	17.03
Dry matter...	79.12	79.73	81.69	84.27	82.26	82.94	82.27	84.05	82.97
In dry matter...									
Albuminoids...	11.72	16.74	12.41	5.95	6.39	18.71	7.97	6.37	7.57
Fat...	6.09	5.15	8.42	18.54	6.39	6.17	5.73	8.66	9.86
Carbo-hydrates...	48.41	51.98	51.00	80.70	52.10	55.24	52.57	55.49	60.81
Fibre...	26.14	10.72	20.46	20.10	28.31	17.74	30.68	29.62	24.83
Mineral matter (ash)...	7.51	7.01	7.55	2.57	8.81	3.40	3.06	4.46	8.43
Nitrogen in dry matter...	1.84	2.08	2.09	0.81	1.03	2.09	1.18	1.05	1.21

PRINCIPAL CONSTITUENTS IN THE ASH—PER CENT.

	Potash	Soda	Lime	Magnesia	Phosphoric acid	Sulphuric acid	Silica
Grey Poplar	14.79	21.60	20.91	12.77	14.80	7.87	12.02
Silver Birch	7.64	7.01	1.14	4.41	1.56	2.17	3.95
Common Alder	24.69	27.19	26.67	31.73	30.80	48.00	27.18
Beech	5.29	6.78	7.99	23.54	6.37	10.70	8.35
Phosphoric acid	4.97	7.56	3.37	3.15	2.44	5.33	4.08
Sulphuric acid	5.07	18.37	6.46	3.81	5.10	3.79	3.43
Silica	23.26	5.40	21.74	5.37	22.05	19.08	22.97

A glance at these figures will show the immense variation in the constituents, and consequently in the manurial value, of different plant leaves, but it must be remembered that a few analyses of plants or their separate organs do not suffice to decide what kind and what amount of plant food a crop needs, and still less in what combination they produce the best effect; they simply tell what kind and amount the plant under examination contains at that particular moment. It is a well established fact that the same variety of plants, whether raised upon different kinds of soil or upon the same soils of a varying degree of richness, may contain a widely differing absolute amount of the same kind of organic "volatile" and inorganic "fixed" constituents. It appears that about 3,000lb. of perfectly dry pine timber are produced with a consumption of only 2½lb. of potash and 1lb. of phosphoric acid per acre per annum; with beech trees the quantities required are rather larger. The growth of trees and shrubs, therefore, is plainly less exhaustive to the soil than ordinary garden culture. The demand on the soil becomes, moreover, considerably greater, if all the fallen leaves are removed.

.*.*

DALMATIA has been regarded as one of the first countries in Europe where the culture of silk became general. It has the advantage of a wonderfully fine climate, and its vegetable products were at one time held in high esteem. Even now it is remarkable for some of its fruit exports. The British Consul at Ragusa, in reporting upon the agriculture of the place, says that the country is well adapted for the rearing of the silkworm and the cultivation of the mulberry. The secret of the production of silk by means of the silkworm was, it is said, long jealously guarded by the Chinese, but was at length disclosed to the Emperor Justinian through the treacherous proceedings of a Princess of China who, on leaving China to marry the Khan of Khofan, managed by the aid of her bridal robes to deceive the vigilance of the guards on the frontier, and for the first time carried the eggs of the silkworm out of the country, and so gave her husband a surprising nuptial gift. About the year 552, by means of missionary monks in Central Asia, Justinian managed to procure a supply of eggs, and in the reign of his son the manufacture of silk in Europe became established.

Under the protection of the Byzantine Emperors, Dalmatia was one of the first countries in which the culture of silk became general, and there can be little doubt that the sacerdotal garment, called the Dalmatic, owes its name to its having been originally fabricated in silk. The cultivation of the silk-worm has, however, been gradually diminishing in Dalmatia, and is still diminishing. One of the chief articles of export of Ragusa in ancient times was dried figs to Venice, and the fig tree is still much cultivated, and the dried fig of Dalmatia is of a very fine quality. The cultivation of the fig has, however, much fallen off since the flourishing period of the provinces. The same may be said of the almond, which also flourishes well. The most esteemed kinds have a tender shell, which can be broken easily with the fingers, and large quantities are exported to other parts of Austria. Both oranges and lemons thrive in the southern parts of Dalmatia, but their cultivation is much neglected. The carob tree is also abundant, and grows wild. Little or no attention is given to the cultivation of garden produce; all vegetables grow pretty much as they will. Asparagus grows wild in abundance in the mountains, but none is grown in the gardens. Lettuce also grows abundantly, but is of inferior quality, for a supply of which Ragusa, with a superior climate, is sometimes dependent on Trieste. The national vegetable is the "kupa," a species of cabbage, which only requires planting once in three years, and requires no attention. The reputation of the flowers of the chrysanthemum cinerariifolium as an insecticide has suffered on account of defective kinds, and the adulterations of it, which have found their way into the market; however, when well selected and prepared, there is no doubt of its efficacy, and it is especially valuable for the protection it affords to costly furs and stuffs against the attacks of moth. The best quality comes from the island of Tesina; the plant is said to thrive better in some localities than in others, and to lose its insecticidal powers out of Dalmatia, where it is indigenous. Another plant which thrives particularly well in Dalmatia is the sumac, which is much used in tanning leather.

IMPREGNATION OF TIMBER.—II.

CHLORIDE of zinc is a good antiseptic for the impregnation of wood. It is, however, not quite so good as sulphate of copper, but it is cheap and on that account not less important than the copper salt. The impregnation with chloride of zinc offers the advantage that the wood does not become hard and can be dressed after the impregnation. Wood impregnated with chloride of zinc will also take coatings of oil paint. Sulphate of zinc would no doubt be as efficacious as chloride of zinc, but it is not employed owing to its being more expensive than chloride of zinc. The per-chloride of mercury or corrosive sublimate has the disadvantage of being extremely poisonous and very costly. Its antiseptic qualities are indisputable. It is used for the preservation of specimens of natural history, pictures, &c. It coagulates albumen most readily. Common salt is well known to have the property of preserving organic substances from decomposition. It has been found that timber in salt mines keeps remarkably well. When salt is employed it must be used in sufficient quantities to prevent its being washed away. Salt is a very good preservative in damp places. When used in too small quantities salt will only have the effect of attracting moisture without protecting the wood. Its application to railway sleepers is rare, though it has been repeatedly recommended for impregnating purposes. Sulphate of iron has been tried in some cases, but is no longer used, other metallic salts having been proved to be superior. Sulphate of iron has the effect of hardening wood. Saltpetre, borax, and arsenic have all more or less antiseptic qualities. A kind of petrification of wood has been produced by a successive impregnation with two different solutions; these solutions being so chosen that they will form a precipitate when mixed. This precipitate remains as an insoluble, in fact, stony, substance, and as it were petrifies the wood. At first sight it would appear that this process might add to the durability of wood, but in actual practice it resulted in nothing, and has been entirely abandoned. The stony particles mixed in the minute cavities of the wood have no chemical action on

the woody fibre, nor can they protect it from moisture. The damp enters the wood almost as freely as if foreign bodies were not present, because these foreign bodies can only partially fill the cavities. The combinations of solutions which have been tried are, alum and alkali, silicate of potash and sulphuric acid, chloride of barium and carbonate of soda, chloride of calcium and sulphate of soda, tin or copper salts and alkali, sulphate of iron and carbonate of soda. Having enumerated the antiseptic substances with which wood is impregnated, it remains to describe the various processes by which the impregnation is performed. They are:—First, the impregnation of wood with vaporous substances; second, the impregnation with fluids. The impregnation of wood with vaporous substances, if practicable, would have very great advantages over the impregnation by fluids. The expediency of making experiments on a large scale with vapour of an antiseptic substance appears therefore exceedingly desirable, and in its own interests and those of the public, Government might direct the Forest Department to take the matter in hand. A patent was taken out in 1855 for impregnating wood by exposing it in a closed chamber to the vapour of creosote. Success is also claimed for a similar process with the vapour of tar. The natural process of impregnation is that with smoke. Wood smoke, containing creosote, when acting a long time on wood, renders the latter exceedingly durable. Open wood fires in huts preserve the timber and straw of the roofs, and are known to preserve from decay even new hay and corn when stored in an insufficiently dry state. A difficulty appears to lie in the high temperature at which carbolic acid boils, viz. 368°. Genuine wood creosote requires even as much as 397°. Wood itself commences to decompose when subjected to a temperature higher than 300°. The creosote must therefore be largely mixed with other vapours and gases to render it volatile at a temperature which is not injurious to the wood. Four different processes are made use of for impregnating wood with liquids:—

1. Spontaneous ascent of the antiseptic fluid in the stem of the living tree, sometimes aided by pressure.
2. Replacement of the sap in felled stems by the antiseptic fluids under hydraulic pressure.
3. Soaking of the wood in the cold or boiling antiseptic fluid.
4. The pneumatic process. Exhaustion of the air from the wood in a boiler, and application of high pressure to force the fluid into the wood.

1. The spontaneous ascent of the antiseptic fluid in the stem of a living tree is brought about in the following way. A hole is bored into the stem at the base, and through a tube which is connected with a cask full of antiseptic fluid, the latter is allowed to flow into the hole. The tree at once commences to 'drink up the fluid. The constant evaporation of water by the leaves causes under ordinary circumstances the rising of water from the roots up into the stem and branches. The antiseptic fluid being, however, offered much more readily than the water supplied by the roots, and as a precaution some of the roots being cut through, the antiseptic fluid alone rises in the stem and spreads during fair weather within twenty-four hours over the whole tree, which, being thus impregnated with sulphate of copper or chloride of zinc, dies in a few days. A similar process is also used with raw pyrolignite (acetate) of iron or copper, common salt, white arsenic, and a solution of resin in oil of turpentine or alcohol. A drawback is the necessity of impregnating the whole tree, and the waste of antiseptic fluid arising therefrom. This is not of much account in view of so cheap a material as chloride of zinc. A more serious obstacle is the difficulty of floating the timber after impregnation.

2. Replacement of the sap in felled stems by the antiseptic fluid under hydraulic pressure.—Newly felled logs are laid horizontally, and one end is fitted up in such a way that the antiseptic fluid can be brought to bear upon the wood under a hydraulic pressure of a column of water thirty feet high. The stems have the bark on them, and the fluid enters the stem and flows towards the other end. As soon as the antiseptic fluid commences to enter at one end the sap of the tree exudes at the other end, and is gradually expelled, the antiseptic fluid taking its place. Moderate sized

trees yield several tons of expelled sap. At first the issuing fluid is pure sap, but after some time a mixture of sap and antiseptic fluid takes place in the interior of the stem, and the two fluids issue together. By continuing the admission of antiseptic fluid the sap is made more and more to disappear, and the result is considered satisfactory when the first fluid which issues from the tree, contains only one-third in sap and two-thirds of antiseptic fluid. The antiseptic substance exclusively used in this process is sulphate of copper. It is employed in a weak solution containing one per cent of salt. Success in this system very much depends upon the kind of wood. The process answers very well with beech; it also does with pine, but is entirely unsuitable to oak; the antiseptic fluid cannot pass through the hard old wood of the oak. Instead of laying the stems horizontally, they may also be placed upright, and the fluid made to enter from above. No oily substance like creosote can be used with this process.

3. The mere soaking of the wood, although very convenient, is of course as a rule a most imperfect process; still there are cases where soaking is resorted to with some success. Some sleepers were immersed in tar for a period of not less than sixty days, and yet they showed scarcely any penetration. Chloride of zinc in solution has been applied to wood by means of soaking, but it was found necessary to adopt a more perfect process. The timber must be immersed two days for every inch in thickness and left to dry after soaking for about twenty days. Heating the fluid lends further aid to impregnation. Thus, wood was artificially dried, and whilst hot, immersed in hot creosote, when it absorbed as much as 9lbs. of creosote per cubic foot. In another instance, sleepers were immersed for four hours in creosote raised to a temperature of 150°, and the impregnation proved fairly satisfactory for such a cheap method. It may be expected that mere soaking succeeds best when the quantity of antiseptic substance is limited. This is the case when perchloride of mercury or corrosive sublimate is used. Corrosive sublimate is very dear, and impregnation is generally effected by soaking sleepers in a solution of it from one to ten days. The solution contains one per cent of the salt or less, and only half an ounce of salt is expended on one cubic foot of impregnated wood.

4. The pneumatic process of impregnation.—This is the most perfect process, and gives satisfaction when others fail. The ordinary requirements of a pneumatic impregnating apparatus are: (1) Two cylindrical boilers of six feet diameter capable of withstanding the pressure of the atmosphere during the evacuation of the air in them, and also of an interior pressure produced by a hydraulic pump worked up to 150lbs. per square inch. (2) An air pump to exhaust the air from the boilers. (3) A water pump. (4) An hydraulic force pump to supply the boilers with fluid up to a pressure of 150lbs. per square inch. (5) An engine of about 10 horse-power to work the pump. (6) Reservoirs for the antiseptic fluid, &c. (7) Tramways to bring the wood on waggons to and from the boilers: the waggons being of such shape that they can be run into the boilers, which are provided with rails and large top pieces for the purpose. There is nothing particular about these requirements which can all be obtained without difficulty. The boilers differ in nothing but their top pieces from the ordinary steam boilers and the air and water pumps are the same as those manufactured for other purposes. Any engine will do, or a water wheel, if there should be sufficient water power available. The tramway, reservoirs, &c., may be constructed as most convenient in each case, so no description of them is necessary. In the pneumatic process the wood is brought to the apparatus in a finished state, it is packed on the waggons and with them pushed into the impregnation boiler and then the lid is closed and made air-tight. If steaming is to take place it is done now before further operations. Steaming of course is only suitable when aqueous solutions are used for impregnation, and when the wood is not already well seasoned; it would never do to steam the wood before the impregnation with oily creosote. The creosote and the oils would mix the water in the wood. If creosote is the substance with which the wood is to be impregnated, the wood may with advantage be subjected to artificial dry heat. After the steaming up to 150° the liquid must be

drawn off which has collected at the bottom of the boiler. When all fluid has left the boiler, the exhaustion of the air by means of the air pump is commenced. The minimum of pressure is reached after half-an-hour's pumping, but the work has to be continued as the wood does not give up its air all at once. After the exhaustion of the air the impregnating fluid is admitted. Creosote is often used in a warm state of 100 to 120 degrees temperature so as to render it more liquid. Whilst the fluid is forced in by superior pressure of the atmosphere, the air-pump must still continue playing, otherwise the rarified air in the boiler would, by being limited to a smaller and gradually decreasing space, become denser and fill the uppermost pieces of timber, rendering them incapable of receiving the impregnating fluid like the other timbers. Care must be taken to avoid overfilling the boiler, because otherwise the antiseptic fluid would get into the air pump. When the boiler is very nearly full, the access of the fluid is stopped, and the compression of the antiseptic fluid in the boiler commences. The force pump drives more and more fluid into the boiler until a pressure of 120lbs. sometimes of 150 pounds per square inch is reached. This pressure is kept up for a time, varying from two to sixteen hours, during which time the wood constantly imbibes fluid. The process is finished up by running the fluid off, opening the head piece of the boiler and taking the waggons out. We commend this enterprise to the attention of the indefatigable firm of Messrs. Groves & Co. Their Ashley works are admirably situated and adapted for the industry which, in time, would develop colossal proportions, and under their able management we are confident the scheme would prove an unqualified success.

The completeness of the impregnation under the foregoing system depends upon the length of time during which the pressure is maintained. As a rule the time allowed for the various operations is such, that the boilers can be filled twice every working day. The pneumatic process is adopted both for creosote and for metallic salts. Sulphate of copper, it must be remembered, cannot be brought into an iron boiler. Factories where the former is used must be provided with costly copper boilers. When creosote is the antiseptic substance employed, the amount taken up by pine and other soft woods is ten to twelve pounds per cubic foot. This amount is considered to be sufficient, and even a smaller quantity of creosote would answer in many cases. Hard woods take up much less creosote. Oak, for instance, takes up only two or three pounds of the oil, even under the heaviest pressure possible. Indian sal wood was penetrated only to one-eighth of an inch from the surface during one particular trial. Sap wood is easier penetrated than old wood in which the circulation of the sap had ceased prior to the felling of the tree. There need be no hesitation as regards the use of impregnated sap wood. If well impregnated it is often found superior to heartwood which has taken up an insufficient quantity of creosote. Examples of woods admitting easy and perfect impregnation are maple, alder, beech, plane, birch, lime. Not quite so easy are pine, fir, larch, poplar, elm. The oak and acacia are scarcely suited for impregnation. The following experiments demonstrate what amount of creosote the harder woods of this country were found to take up:—

	Pounds of creosote per cubic foot
Sassu	3½
Sundri	2½
Teak	1½
Sal	1
Ironwood	1
Mahogany	0½
Jaman	0½

Experiments with aqueous solutions of chloride of zinc confirm the results obtained from creosote, the hard wood taking up much less than the soft wood. The following shows the quantity of solution of chloride of zinc taken up under the pneumatic treatment by different kinds of wood:—

1 cubic foot of pine wood	15 lbs. solution.
1 do. " beech "	15 " "
1 do. " oak "	8 " "

The small capability of some hard woods to take up antiseptic fluids is of little consequence so long as these hard woods are able to endure unimpregnated, for the same length of time. This is more or less the case with oak in Europe and with sal and teak in this country. Sal and teak, as also deodar, are used unimpregnated for sleepers in India. The class of woods which require impregnation are pines (*Pinus longifolia*, *P. excelsa*, *Pinus Smithiana*) which are capable of taking up a full quantity of creosote or other antiseptic fluid. These light and less valuable timbers can thus be impregnated and rendered as durable as the superior deodar, sal, and teak. We find that of all the methods enumerated for the impregnation of railway sleepers, only three have to be considered. These are (1) creosoting: that is, the impregnation with common creosote by means of the pneumatic process. (2.) The method of introducing a solution of sulphate of copper by means of replacement of the sap in felled stems. (3.) The method of introducing a solution of chloride of zinc with the pneumatic process. A fourth method, viz, soaking the wood in a solution of corrosive sublimate comes next to the above three in importance, but the material is too expensive. Among the above three methods, creosoting stands foremost. It is the best antiseptic, and increases rather than diminishes the strength of soft wood, its effect being thus contrary to that of metallic salts. It resists more than other substances the lixiviating action of the water. Creosote, when used with the pneumatic process, doubles the durability of soft woods, and there is no risk of failures. Creosote also keeps off white ants, and creosoted sleepers are admirably adapted for India. The method of sap-replacement by means of sulphate of copper solution would not be generally applicable in this country, because the wood has to be floated and takes a long time to reach its destination. The use of Chloride of zinc has the disadvantage of rapidly corroding iron, and consequently the nails soon become loose in sleepers impregnated with this substance. Yet this salt would be the one to substitute in the absence of creosote. The pneumatic is undoubtedly the most advantageous process. Apparatus and machines for the latter, such as we have described, could be procured and set up for about Rs. 12,000, all costs included. The price of substances used for impregnation naturally varies considerably. The following European prices are therefore to be taken only as approximate, and intended to give a general idea of the cost of antiseptics used for impregnation:—

PRICES PER TON IN EUROPE.

	£
Creosote	4
Chloride of zinc	10
Sulphate of copper	50
Per chloride of mercury	500

The total cost of impregnation varies even more than the price of the materials. The following data will give some idea of the cost of impregnating pinewood:—

	Pence.
Creosote by the pneumatic process, per c. f.	4.
Chloride of zinc do. do. c. f.	2.
Sulphate of copper by sap-replacement, per c. f.	4.
Per chloride of mercury by soaking only, per c. f.	4.

The cost of creosoting sleepers in India depends entirely upon the rate at which creosote can be imported from England, as there is at present no material with which to replace English creosote. Ship-owners dislike creosote as a cargo, for it necessitates the exclusion of other goods from the hold, and the same objection applies to the shipping of creosoted sleepers from England. Pine creosoted sleepers can be imported from England to Madras at 7s. 3d. per sleeper. It would be very desirable if Indian sleepers could be creosoted with some material procurable in the country. There are, however, no data at present to show whether any substance can be obtained cheap enough to compete with creosote imported from England. In this country, coal tar from the Gas Works is sold at the prohibitive price of Rs. 45 per ton. This is almost as much as the price of English creosote sold at Madras, and besides this high price, only about 25 per cent. of the Indian coal-tar would be efficacious for impregnation. The use of Burmese earth-oil has been suggested, but there are no data to show

whether earth-oil would act as a sufficiently good preservative, nor would Burmese earth-oil be much cheaper than creosote from England. The products of distillation from wood might be used instead of coal-tar oil. In Europe good wood-tar is procurable at £10 per ton, we fail to see why it should not be manufactured in this country for the same price. Wood-tar oil might even be dearer than creosote and still compete with the creosote, because the produce of the wood contains more of the valuable real antiseptic substance, than the produce of coal does. For the same reason wood-tar oil would be an excellent material to mix with English creosote. The question of the manufacture of wood creosote in India recommends itself as a subject of special enquiry. This much is certain, it is highly desirable to creosote in India sleepers from inferior Indian woods, wherever there is not an abundance of superior woods, and where, at the same time, the distance from seaports and the coast renders importation from England of creosoted sleepers so expensive as to make it almost impossible.

INSECT PESTS OF INDIA.

A FEW days ago one of our native contemporaries (*Reis and Raynot*) blamed the Government of India for its apathy, and tardiness in the matter of introducing some useful measures for the destruction and extermination of insects injurious to food-crops and fruits, and cited the mango-worm as an instance of the havoc caused by this pest to one of the finest fruits of the country. "The fly is so tenacious of life that it thrives within the heart of the fruit. You cut a fruit apparently sound, without a spot on the surface, when, lo! the fly issues out of the interior and buzzes past you. These insects have degraded the East Bengal mango for at least more than half-a-century, and yet no notice has been taken of the matter." Another of our contemporaries (*Indian Daily News*) affected to treat this important subject facetiously, and asked why there should "not be a native Lubbock to enquire into these matters." While agreeing generally in the views of the *Indian Daily News* so far as they relate to entomological investigations being advantageously undertaken by learned country gentlemen (natives) having plenty of time at their disposal, "who might thus render a service to the people while engaging themselves in an interesting pursuit," we are decidedly of opinion that unless the Government initiates measures having for their object the destruction and extermination of insect pests, it is not likely that the native community will do much—or anything—in the matter. For many years it was found almost impossible to collect accurate statistics of the various staple crops of the country. The first step to supply this want was taken in the North-Western Provinces, by the local Government taking into its confidence the various landholders, zemindars, talukdars, &c., and inviting their co-operation. With what success the system has worked, need not be adverted to here; the report published by us last week of the Agricultural Exhibition at Lucknow, will have given our readers a fair idea of the satisfactory results obtained. In the same way, we think the Government should invite the co-operation of native gentlemen, landholders, zemindars, and others in a matter of such importance as the destruction and extermination of insect pests. That the subject is a very important one, will be recognised by those who have studied the entomological reports of other countries, and the enormous losses annually sustained by farmers, both at home and abroad, by the depredations of insect pests. So far as the matter relates to India, it has attracted attention at home, and has given rise to a correspondence between Surgeon-General E. Balfour, author of the *Cyclopædia of India*, and the India Office. In a letter, dated 8th August 1885, to the Under-Secretary of State for India, Dr. Balfour said:

The article "Insects" in the 3rd edition of the "Cyclopædia of India and of Eastern and Southern Asia," is, I think, the first attempt to give a general view of the entomology of that wide region. This is, in many ways, a very difficult branch of natural history; but this article was prepared and printed by me under the care of two scientific men, one of them ranking among the most learned of living entomologists, and I was favoured also with counsel from Miss Ormerod, who, in this country, annually reports on the insects injurious to food-crops, forest trees, and

fruits, and the prevention of insect ravages. The like of Miss Ormerod's form of reporting has never been done for India. Although every year, to some extent, and from time to time largely, losses occur there from the pests which attack agricultural produce, India has hitherto been remiss in this matter, contenting itself with references as to individual insects or blights to such persons as were thought likely to be able to give information. But the subject is of far too great importance to agricultural India to be left to be treated in so casual a manner, and the special knowledge now available might be utilised to describe the insects which injure the agricultural, horticultural, and forest produce of India, suggesting means of preventing, and remedies for same. The reports should be restricted rigidly to the injurious insects, and should be half-yearly, to fit in with the two great agricultural seasons.

Dr. Balfour was informed in reply that a copy of his letter had been forwarded to the Government of India. Later on, he informed the Under-Secretary of State that he had communicated with Miss Ormerod on the subject, who had expressed her willingness to render the movement any service that lies in her power. Miss Ormerod is so well known in the entomological world that her opinions will, we have no doubt, carry the weight of conviction. She is Consulting Entomologist to the Royal Agricultural Society of England, and this is what she says in her letter to Dr. Balfour :—

I am very much obliged to you for favouring me with a copy to your letter to the Under-Secretary of State for India, relative to the importance of acquiring serviceable information regarding the injurious crop insects of India, and also kindly giving me a copy of the official reply. I do not see that you could do better, as a commencement, than thus bring the subject shortly and clearly forward; and, as far as I can form an opinion, I think that the course you suggest would be the constant means of saving thousands of pounds yearly—occasionally (perhaps more than occasionally) of saving millions. I found this opinion, of course, on consideration of the unremunerative outlay so often occurring on some of the great crops, notably (as coming specially under my notice) the loss by ravage of coffee plant grubs. The information that is needed could be given by plain and simple jotting down by various persons of what they themselves have observed. One man notices, perhaps, how deep the grubs go; another, how long they live; and so, by collating the points, we get to know the whole history of habits, which is what is needed to work on. It may take a few years to get the whole life-history of the insects, but we soon get in the way mentioned above (on which plan my own reports are formed) to learn the main points, and then all observers are requested to find the missing part of the history. If reports were formed in this way, there would very shortly be a great increase of useful knowledge throughout the Indian Empire. I present my reports yearly to the contributors, thus they take a personal interest in the work, and, what is immensely important in things of this kind, the book comes to them on publication; they have not the trouble of ordering it. The expense would be a mere nothing to Government, seeing that I, a private individual, have now for eight years, without the slightest assistance, carried on the work in England. The great mistake is in waiting until attack is unusually destructive, and then consulting those who, though eminently skilled in classification of insects, have no idea, or well founded knowledge of the points of agricultural treatment or forestry which must be brought to bear on the insects in some special stage of their life. Likewise (as occurred not long ago) to advise reliance on the insectivorous animals of England for help in India or Ceylon is a decided mistake. If, from the long experience which I have now had of gaining information on insect attack, and forming it into readable shape, you think any suggestions on my part would be of service, I should be most happy to give my attention in my power to the subject. But, meanwhile, I may most truly say that if the crop, or timber, or fruit growers of India were furnished with plain and comprehensive accounts of the history and habits of the common insect pests, accompanied by woodcut figures, so as to convey the appearance of the pests without wearisome descriptions of details, that all this would be a national benefit, soon paying the outlay hundreds of times over.

It is satisfactory to know that the India Office has taken the matter in hand, and has transmitted a copy of the correspondence to the Government of India, who, we hope, will take proper steps to initiate measures for the dissemination of entomological knowledge on the plan suggested by Miss

Ormerod, and the collection of accurate reports on a matter so vitally affecting the welfare of agriculture in India.

MEDICINAL AND OTHER USES OF THE EUCALYPTUS.

The Agricultural Department of the Government of Madras has been at some pains to draw up a memorandum, comprising extracts* from various sources, relating to the medicinal uses and other virtues of the Eucalyptus order of trees, commonly known as the "Australian Blue-Gums." The many valuable properties possessed by this genus of trees have attracted a large share of public attention; and although a good deal of these properties have come to be well known, new and important uses are being found for the leaves in various forms. The information collected by the Agricultural Department is very interesting. The memorandum opens with an extract from *Bargoyne, Burbidge and Co's Circular*, in which it is stated that "the oil of *Eucalyptus globulus*, as a substitute for carbolic acid, has been much advocated of late. It is a most valuable antiseptic, and has obtained the happiest results in bronchial catarrh. Professor Lister is of opinion that the *Eucalyptus globulus* should supersede carbolic acid as an antiseptic because of its harmless nature." The *Companion to the British Pharmacopoeia* is also quoted, in which it is said that "liquid extract of *Eucalyptus* gum 1 part, water 2 parts, dissolved and strained, is an excellent remedy in arresting bleeding from the nose. Lint dipped in it checks bleeding from wounds. The gum is used in doses of 5 grains every four hours in diarrhoea and dysentery. The oil is obtained from the leaves by distillation." The *Medical Times and Gazette*, in an issue of 1882, in noticing the *Eucalyptus Globulus*, stated that the oil is said to diminish the action of the heart and the blood pressure, and to act as a stimulant, astringent, and antiseptic on mucous membranes. Dr. Currier spoke highly of its use as a disinfectant and antiseptic in chronic ovaritis and tumours of the breast, in removing the factor of the discharges, and relieving the pain and discomfort. The *Export Prices Current and Trade Report*, in an issue some time back, observed that "the leaves of several of the species, when duly prepared and compounded into an ointment, are found to possess, healing properties, which, without exaggeration, may be termed remarkable. Josephson's ointment is the property of Messrs. E. Row and Co. of New South Wales. In the colonies it has achieved, we believe, considerable success in the treatment of wounds, &c." Dr. J. M. Gibbs, Coroner of New Zealand, in an article addressed to the *Australian Medical Gazette*, during a severe epidemic outbreak of diphtheria, recommended the following treatment for this horrible disease: "First.—After swabbing the throat with liq. fer. perchl. dil. and glycerine. Second.—Pour boiling water on blue-gum leaves and let the steam be inhaled day and night. Drawing steam through an inhaler, or holding the head over a jug, is a most wearisome process, and you find that patients, especially children, soon get tired of it; so I order the pan, jar or jug containing the infusion to be placed on a chair besides the bed, and a tent of the bed-clothes to be placed over it and the patient's head. This conveys the steam to the patient without exhausting him. Children soon feel the soothing effect, all uneasiness and pain in the throat leaving. Of course in mild cases the steam does not require to be used so often. In several cases, after 5 or 6 hours' steaming, complete casts of the air-passage were coughed up, and the breathing became easy at once. One young lady tapping the upper part of her sternum, said, 'It is here.' She could not swallow a tea-spoonful of water! Her lips were blue and her face of a dusky hue; but after hours of steaming the membrane was coughed up, and the breathing became at once easy. In one case, where steaming was not carried out, the little patient was semi-asphyxiated for three days before death put an end to her sufferings. It was the first case of this epidemic that I saw, and was not able to sufficiently impress the attendants with the importance of the constant use of this steam. In blue-gum steam we have a most perfect disinfectant, as in no single case,

* We have arranged these so as to run one into another.—ED., I 4.

after the first twenty-four hours, was the breath unpleasant, and the swelling in the neck quickly subsided. Towards eight o'clock the diphtheria patients generally became feverish, restless and unable to sleep, and it was wonderful to watch the soothing effects of the steam. A bucket was generally placed in the room containing the blue-gum water, and a red-hot poker placed in it, which at once filled the room with steam, and very shortly after one child after another would fall asleep. Twenty-four cases were treated as above, with the death of only one infant, aged eight months. There were six other children ill in the same family, and not one case of paralysis has occurred amongst them, although two treated with sulphur by their parents are badly affected. I think that I can claim for the above treatment—

1st.—Great simplicity.

2nd.—That it follows nature's own method of getting rid of the membrane, namely, by suppuration.

3rd.—That it prevents paralysis from following.

4th.—That it cures the severest cases."

Dr. Ross, M. D., in a letter to the *Sydney Mail*, describes an extraordinary cure of a wound. He prefaces his letter with the following remarks: "I am forced, from careful observation and long experience of bush life, to believe that the majority of our gum trees, no matter in what form used, whether in the shape of their leaves in their natural state, or dried, in ointment, powder, decoction, gum, extract, oil or alkaloid, all inherit virtues. Time alone is bound to bring them into more general repute as an invaluable antiseptic and agent for counteracting lethal or poisonous exhalations; a cooling, healing application to wounds and ulcers, or rheumatism and a salutary remedy in parasitic disorders in sheep." "I shall now," he goes on to say, "submit the following short extract of a remarkable spear wound case:—On the 28th December 1864, I found the abdominal wound wide open and gaping, and the bowels protruding, accompanied by a quantity of ichorous serum oozing from the large orifice. Had taken no medicine. His gin, sitting by his side, in the bough ganyah, attentively bathed the wound and swollen abdomen with a few of the most tender shoots and leaves of the red-gum tree, steeped from time to time in hot-water. In consequence of the untoward appearance of the wound all chances of his recovery seemed now to have been quite taken out of my hands, for to attempt to close the wound, under the circumstances, would not only have been perfectly futile, but have added to the danger as the swelling was rapidly increasing, so much so that the case appeared quite hopeless and the pulse was sinking. On returning in the evening, I found to my great surprise and astonishment that what I had considered to be a useless and cruel sort of application had not only lessened the size of the wound, but had positively had the effect of reducing the swelling. Seeing such results, of course I could make no further objection to the use of this strange application in the shape of gum-tree leaves, and the sixth day found the abdominal wound closed!"

The *Extra Pharmacopœia*, 1884, has the following:—

Eucalyptus foliæ (Eucalyptus leaves).—Dose five grains, or more, in powder. The dried leaves of the *Eucalyptus globulus*, or blue-gum tree of Australia, have been employed medicinally in the treatment of ague and bronchitis, and are now much used in Italy for Roman and malarious fevers; also, when coarsely powdered, are employed for smoking in cigarettes in cardiac and aneurismal asthma. The narrow leaves, mostly scimitar shaped, are more active medicinally than the broad leaves of herbaceous shoots.

Oilum Eucalypti.—Dose 1 to 5 minims emulsified with olive oil. Is distilled from the leaves of the *Eucalyptus amygdalince* and also from those of the *Eucalyptus globulus*, and probably from other species. It is to this oil, and also especially to the great avidity for water which this tree has when growing, that it owes its anti-malarial influence. The oil is a powerful antiseptic, and has an astringent influence on the atmosphere while it oxidises. It has a pale yellow color, a penetrating, camphoraceous odour, sp. gr. about 0.900, and boils between 338° and 392° (Fahr). It is not caustic like carbolic acid, nor does it produce much irritation, although it is very destructive to low organic growths. It is soluble in oils, fat, paraffins, and alcohol, but only a trace dissolves in water. The oil is useful (mixed with an equal quantity of

olive oil as a rubefacient for rheumatism. A large percentage of *Eucalyptus* oil consists of "*Eucalyptol*," which is also met with in commerce, and is that part of the above oil which passes over between 338° and 352° F. It is obtained by treating the latter with caustic potash, then with chloride of calcium, and subsequent distillation.

The following extract, taken from the *Australasian*, enumerates the manifold virtues of this remarkable genus of plants:—

Baron Von Mueller has been at the pains of collecting and collating testimony from the scientific publications of many countries, and he cites recorded cases resting on the authority of practitioners of eminence to show that *Eucalyptus* oil possesses almost unique virtues as an antiseptic, as an agent for the reduction of the pulse in phthisis and typhus, for the diminution of bronchial catarrh, for combating insipient or threatened gangrene, and for healing certain ulcers. Dr. Wooster, of San Francisco, enumerates 129 cases of various diseases, 96 of which were cured by the administration of the fluid extract of *Eucalyptus* foliage. In 23 cases of remittent, intermittent, and typhoid fever every one yielded to the treatment. The American Faculty are using the extract largely in cases of diphtheria and scarlatina with the most gratifying results; and in severe cases of cystitis, it has effected cures when all ordinary remedies had failed. In the practice of a single physician in New York, 100 diphtheritic cases have been successfully treated by the fluid extract. *Eucalyptus* inhalations, it has been found, are capable of overcoming catarrhal asthma and whooping cough, and of arresting pulmonary consumption.

The *Pharm. Zeitung*, a German paper, says:—

Rodolfo Rodolf recommends, from personal experience, the chewing of two or three dried leaves of *Eucalyptus globulus* as a sovereign remedy for cold in the head and coryza, provided they are recent and not chronic. The effect generally makes itself felt in half-an-hour.

As an instance of some of the novel uses to which *Eucalyptus* Oil has been put, other than medicinal, the following paragraph was published some time back in the columns of the *Indian Agriculturist*:—

A process has been invented in America for the manufacture of a preparation of the gum of the *Eucalyptus globulus*. It has the effect of removing thoroughly the scales which form in engine boilers, and thus prevents rust and pitting. The result of the introduction of this preparation has been so great as to create an immense demand for it both in America and Europe. The effect of this preparation in preventing the pitting and corrosion of boilers will, it is expected, extend the period of their usefulness 100 to 150 per cent, and at the same time effect a great saving in fuel, as scale is a non-conductor of heat, and therefore more fuel is required to generate steam in old boilers than in new clean boilers.

The Director, Government Cinchona Plantations, Parks and Gardens, Nilgiris, furnished the following method of obtaining the oil from the leaves of the *Eucalyptus globulus*:—

"The leaves of many of the *Eucalypti* yield very good oils, and few are more valuable than that obtainable from the *Eucalyptus globulus*. The way to extract the oil is as follows:—Fill a large still with the macerated crushed leaves and water, and distill at a low temperature. Shake up the product with a little salt (this causes the oil to separate more rapidly from the water which comes over with it from the still), decant the oil from the water, and filter through the paper. The leaves should be macerated for twenty-four hours, and then mashed up. This process facilitates the extraction of the oil by breaking down the cells which surround the glands that contain it."

It will thus be seen from the foregoing that the *Eucalyptus* order holds a high place in the medical world. Steps were taken some years ago, when the valuable properties of the *Eucalyptus globulus* were first made known in this country, to cultivate the tree all over India, as a means of ascertaining whether it would succeed here. Constant mention is made of these trees in the annual reports of the various Botanical and Agri-horticultural Gardens; and although their cultivation has not been attended with unqualified success, yet sufficient is known to warrant the hope that in time the *Eucalypti* may become completely acclimatized in India.

Miscellaneous Items.

On the 30th of September there were no less than 197,748 persons employed on the various railways in India. Of these, 189,439 were natives, 4,669 were Europeans, and 4,250 Khat Indians. This shows that 95.79 per cent of the entire number of employees were natives.

THE quantity of salt of every description cleared during the second quarter of the current year was 28,51,562 maunds, against 26,41,346 maunds in the corresponding quarter of last year. The nett amount of duty levied was Rs. 25,41,617, against Rs. 50,17,357 in the corresponding quarter of the previous year.

THE opium revenue for the year promises well, although the actual returns for Bombay in November were worse than the estimate by Rs. 10,23,650. Taking the eight months of the year that have elapsed, the Bombay pass duty shows a total advance upon the estimates of Rs. 15,23,475; while in Bengal, on the other hand, there has been a total falling off in the sales of upwards of two lakhs.

THE complaint raised by the proprietors of the salt pans at Goa that the indemnity due has not been paid by the British Government is much commented upon by the Goa press. It now turns out that the delay was due to the Portuguese rather than the British Government. In accordance with the provisions of the Luso-English Treaty the Goa old money was received at the Bombay Mint, and bills were eventually submitted for payment, of which the Treasury of Goa took no notice. The reminders that were sent from time to time did not receive any better attention. So the payment of the expenses of recoining, amounting to some ninety thousand rupees, was put off until the British Government, growing impatient of the delay, intimated that, if the amount were not paid off at once, it would be deducted from the indemnity due to the salt-pan proprietors. The Treasury Department of Goa was taken aback by this unexpected arrangement, but having no plausible excuse to offer, meekly acquiesced. So far good, says a correspondent. But what about the salt-pan proprietors? The poor fellows will have to wait perhaps years before they get their dues.

A CONTEMPORARY says:—Our readers may possibly recollect that two or three years ago, the attention of the Government of India was drawn to the extraordinary and increasing number of notices of ejectment that are annually served upon the tenants in Oudh. It is a peculiarity of the Oudh Rent Law that an immense majority of the tenants in the province hold on a yearly tenure, and are liable to ejectment upon very brief notice every twelve months, at the pleasure of the landlord. There can be no doubt that such a system is disadvantageous to the joint interests of both landlord and tenant, since it has been pronounced detrimental to agriculture by all authorities on land tenure, although, like every other system, in the hands of a good landlord, it may be worked without much positive mischief. Lord Ripon's Government took up the question rather warmly; some official investigations were made in all the Oudh districts, and after the usual protracted discussion the whole correspondence went home to the Secretary of State. We believe that the local Government has now at last been authorised to bring certain definite proposals to the test of practical discussion, and to frame some amendments of the present Rent Law that will give greater stability to agricultural holdings in Oudh, upon the basis of an extension of the term within which tenants shall be exempt from arbitrary ejectment, with some limitation for the present unlimited right of enhancement. There is good ground for believing that the talukdars will be found willing to acquiesce in any such scheme of reasonable reform. Indeed, in these times of heroic remedies for agrarian distress, when the wildest projects for disempowering landlords and distributing the land are afloat in Ireland, and even in England, and advocated by leading politicians, there is manifest wisdom in showing a disposition to accept and expedite any proposals for prudent and moderate reforms. If, especially, these reforms avoid reviving old disputes about hereditary tenant right, and are chiefly directed towards the equitable regulation of agricultural contracts, with the object of giving a tenant sufficient time for improving his land and adequate security for his investments, it is difficult to suppose that they can meet with any material or well-founded objection from any quarter.

PARASITES AFFECTING ANIMALS.

STRONGYLUS FILARIA AND STRONGYLUS CONTORTUS IN SHEEP.

THE following paper, as briefly noticed last week, was read at a meeting of the Galawater Farmers' Club the other day by Mr. W. D. Connochie, V.S., M. R. C. V. S., Selkirk:—

Before proceeding with the subject upon which I have chosen to address you to-night, I must offer an apology for any inconvenience or disappointment I caused the members of the Galawater Farmers' Club in not being able to fulfil my engagement at their last meeting. Exigencies of a peculiar kind, and which I could not control, precluded me from being present at that time, therefore the necessities of the case is my apology. However, I am here to-night to atone for any shortcomings on that occasion, and will endeavour, however inadequately, to fulfil the promise that I then made.

ANIMAL PARASITES.

The subject that I have chosen to bring under your notice is a wide one. The number and variety of parasites affecting animals externally and internally are exceedingly numerous. I find that to attempt a classification of the different orders, and to enumerate every known species of parasite affecting animals, would be a weariness to you, and serve no useful purpose.

In classifying parasites, they are generally described as Ecto-parasites when they infest the internal organs, such as the stomach and bowels, lungs, liver, kidneys, &c., and as Ecto-parasites when found on the external surface of the body. The appearances presented by animals affected with external parasites are familiar to most of you; therefore, I do not intend to notice them further now, but purpose to confine myself to the consideration of one or two of the more important of the internal parasites, or Entozoa, familiarly known as worms, whose frequent occurrence in the animal body, and the variety of disorders which accompany and flow from their presence, demand the utmost attention from every stock-owner and the special study of every veterinary practitioner.

The occupancy of animal bodies by parasites presents a very remarkable and very little understood feature in the laws of nature, for it does appear to be a principle in the economy of nature that almost every species of animals, either during life or after death, shall be subject to the incursions of some other species. It is difficult to find a satisfactory explanation for any such law, unless it be a provision for the fulfilment of another recognised principle of nature, that every situation which is capable of sustaining living beings shall be peopled with them.

There are at least six orders of parasites which have a special interest to stock-owners and veterinary practitioners, viz.—*Nematoda*, *Trematoda*, *Cestoda*, *Acanthocephala*, *Diptera*, and *Fracharia*.

Nematoda, or round worms, of which the *Strongylus filaria* and *Strongylus contortus* are examples, whose general appearances and mode of development in the different situations in which they are found, together with the symptoms presented by animals infested with them, the morbid conditions connected with their presence, and lastly, their treatment, curative and preventive, I purpose to consider as concisely as possible.

Strongylus filaria is that small round thread worm of a yellowish white colour, from 1 to 2½ inches long, found in the air passages and lung tissue of lambs and young sheep, and which are the cause of that serious and destructive malady termed 'the lamb disease.' Another parasite of a similar appearance, the *Strongylus miorurus*, is the cause of the disease in calves and young cattle termed 'hoose or husk,' from the animal suffering from them being subject to violent and convulsive fits of coughing. The pig is also infested with a similar worm which is termed *Strongylus suis*. Although all these strongyli present under the microscope a slight difference in their anatomical formation, they have all a certain character in common, so that a description of one of them is sufficient for all practical purposes.

Through the usual courtesies of Mr. Owen Williams, Professor of Morbid Anatomy in the New Veterinary College, Edinburgh, who has made these parasites a special study, I am enabled to show you a specimen of each of these preserved in spirits. As I stated before, you will observe that they vary in length and thickness, having a uniform body tapering towards each extremity unless in the case of the female, which, when pregnant, assumes a sort of barrel form. It is a singular fact, and one worth recording, that the females of the strongyli as in the case of females in the higher order of being, largely predominate over the opposite sex. When we observe the extraordinary development of the reproductive organs, we cease to wonder at the rapidity of their reproduction. How they originated or were reproduced was long a subject of controversy. Their origin has all along, and is still involved in

much obscurity, though recently their reproduction and development have been pretty clearly demonstrated by Dr. Cobbold, of London, who has given more attention to this special study than any living writer, at least in this country. But even he is forced to admit that 'with the exception of *Trichina spiralis*, I am not aware that we have a thorough knowledge of the entire life-history of any of the Nematode species which infest the human body, nor, indeed, can I call to mind any round worm infesting the lower animals, whose life phases, migrations, and peculiarities of structure during development are satisfactorily known.' That being so, it would be altogether unprofitable for me, in a popular essay, to enter at any length upon a question involving so much speculation. It will be sufficient if a few of the more important points which have been advanced are noticed. Some have contended for their spontaneous generation within the body, due to a diseased condition of the tissues. Some have contended for their external origin in all cases; whilst others again, amongst whom are the most recent observers, maintain that the ova and young parasites are conveyed with the food and water into the alimentary canal, where they become absorbed into the circulation, and thence conveyed in the blood stream to the different situations where they find a suitable nidus for their development.

SYMPTOMS.

The symptoms presented by animals suffering from *Strongylus filaria* differ according to the severity of the attack and the different organs affected with them. If the lungs and respiratory passages are alone infested, the peculiar cough accompanying their presence will be the characteristic symptom, which, when once heard, is not readily forgot. Those of you who have had the unfortunate experience of these filaria infesting your flocks cannot have failed to observe the distressing nature of the cough and the sounds emitted in connection with it. I have, when standing in the midst of a large flock of diseased sheep, compared it to nothing less than the meeting of contending armies. You have every sound, from the rattle of musketry to the roar of the cannon, even from the moans of the wounded to the groans of the dying. If, as is often the case, the parasites infest also the stomach and bowels, then the symptoms are more complex. In addition to the cough, there will be indications of abdominal pain, grinding of the teeth, insatiable thirst, diarrhoea, or dysentery, with hectic fever. These will differ in severity, according to the particular organ they infest and the degree of impairment to its functions caused by their presence. It is a remarkable fact that the body may be infested by thousands of worms, and yet no symptoms whatever manifest themselves, so that their existence is not even suspected. This is the case with the *Trichina spiralis*, whose seat is the muscular system of the human race. They may exist in such numbers as to defy enumeration, yet their presence does not seem in the least to impair the functions of the part in which they are imbedded, and as mentioned by Professor Williams, sheep have been killed in prime condition by the butcher and their lungs found loaded with filaria. If the above-mentioned symptoms increase in severity, in addition will appear rapid wasting of condition, impaired or total loss of appetite, enlarged abdomen, and anaemia, when death ends all.

MORBID APPEARANCES.

On making a *post mortem* examination on the carcass of an animal which has succumbed from these parasites, if the lungs have been the seat of these worms, they will be found covered with numerous nodules varying in size and hardness according to the length of time they have existed. When these nodules are cut into, they will be found to contain worms of various sizes, coiled upon themselves. When occupying the intestinal tract they will be found in bundles coiled upon themselves, and covered with mucus. The accumulation of mucus in the intestines when these parasites are present has led certain investigators to believe that it was the cause instead of the consequence of their presence.

TREATMENT.

We now come to treat of what to stock-owners at least may be considered the most important part of the subject, viz., the destruction and expulsion of these parasites from animals when infested with them and the prevention of their recurrence, or of gaining access into the system. When any of the filaria have once gained access to any of the organs which they inhabit, it is often very difficult to effect their expulsion. Many have been the medicinal agents recommended for that purpose, but, unfortunately, after trying most of them, the result proves anything but satisfactory; and that is not to be wondered at, seeing that, from the situation of many of the organs infested, medicines only can reach them indirectly through the circulation of the blood, and it is only those which occupy the stomach and bowels that may be considered directly within the range of medicinal agents. Of all the medicines that have been tried for the expulsion of worms, the oil of turpentine, along with any of the bland oils, constitutes one of the best vermifuges, because it not only acts as a poison to the parasite, but also as an evacuant, thereby clearing the alimentary tract from all accumulations of mucus which seem to act as a nidus favourable to their development. This medicine is easily administered in the case of cattle, or when only a few sheep are affected, but when whole herds or flocks are affected it is almost hopeless to attempt it. We must then have recourse to medicines which are comparatively tasteless. Chloride of sodium—common salt—by itself among the food, or in combination with one of the preparations of iron, has proved of considerable efficacy. For several years I have used with good results a preparation composed as follows:—Sulphate of iron 15 grains, tartaric acid of antimony 10 grains, nitrate of potash 20 grains. This is a dose for a sheep, one to be given each day mixed in their food of crushed corn, cake

and bran. Along with the medicine and hand feeding it is imperative that the animals be moved to a different pasture, and one that has not been grazed over before by older animals, and as the disease is neither hereditary nor contagious, the older animals may graze on the pastures the younger one has left with impunity. If these remedies fail to have the desired effect we must have recourse to other measures. And indeed where the air passages are alone affected, it is necessary that we should have resort to the inhalations of chlorine or sulphurous acid gas. This can be effected by having the animals in an enclosed building and setting fire to sulphur in their midst, taking care that the fumes are not too strong or continued for long so as to cause suffocation. This can be prevented by opening the door and letting in a quantity of external air. About a pound of sulphur to 60 sheep and the time they should be confined 20 minutes, of course much depending on the size and close state of the building.

Another remedy which has only very recently been brought under notice for the destruction of parasites in the air passage is the direct introduction into the trachea or windpipe of agents such as carbolic acid, creosote, turpentine, or prussic acid, with a small syringe, which operation is termed intra-tracheal injection. But as the operation, though simple, requires a professional or at least one who knows something of anatomy, to perform it, it is not necessary for me to notice it further now. It now remains for me to notice what can be done by way of preventing the introduction to, and development within the system. As already stated, it is very difficult to destroy or eradicate parasites after they have gained access to any organ. It is of the utmost importance to prevent their doing so. Although we do not yet know all the places and migrations which these parasites undergo before they reach their several situations in the animal system, we do know that they are the inhabitants of low-lying damp, marshy ground, and of stagnant pools and ditches; from these they are distributed over the pastures in wet seasons, and are there taken into the system along with the food. Hence the necessity of preventing animals, especially lambs and calves, from feeding upon such places. When lambs are weakly it is a *sine qua non* of their existence that they be placed on dry, clean, and fresh grass, which has not been grazed over by older sheep. In addition to these measures, I attach the greatest importance to the top dressing of the land with lime or salt, especially salt. I am convinced that if tracts of rank, coarse, indigestible herbage were periodically burned, and from 6 to 8 cwt per acre of crushed rock salt applied, the mortality and loss from parasitic diseases would be greatly lessened. I do not advise whole stretches of pasture to be sown over with salt, but two or three acres at intervals, so that animals could have their choice of what to feed upon; salt being the natural stimulant of the digestive organs in animals as well as man, they should always have free access to it. But besides acting as a stimulant to the digestive organs, by applying it to land in the manner described, it has the effect of destroying the parasites either in the ova or larval state. Taking into the manual value of salt into account, I often wonder that it is not more used for that alone. I sometimes think that it is its cheapness that militates greatly against its more general use. For their own profit agriculturists should still look upon it as the salt of the earth.

The *Strongylus contortus* is a habitant of the fourth stomach of the sheep and goat, and is the cause of the disease termed 'parasitic gastric catarrh.' Through the kindness of Professor Williams, I am enabled also to show you a specimen of them. These were found in the fourth stomach of a sheep belonging to Mr. Elliot of Hollybush, where Professor Williams was called in consultation with myself. These are the only specimens of the *contortus* that I have seen. I believe that to Professor Williams is due the credit of either seeing or describing it, in this country at least. You will observe that they very closely resemble the filaria, with which they are often found consorting together, and it is the opinion of Gerlach, an eminent Prussian veterinary surgeon, that they are much akin. Professor Williams says:—'It is now believed that the ova of these parasites, passed from the body of their host, retain their vitality in damp places only, and that where mice bites of green grass, such as that growing on the sides of open drains, and damp spots on pastures otherwise dry, are sources of danger, the parasitic ova becoming infested with such grasses. The prevention of the disease by destruction of the worms should be attempted by first digging up, where possible, all such green grasses, and inverting the sods; second, by a liberal application of salt to the land, and, where possible, an allowance of it to the sheep. During wet seasons the above precautions are impossible, and all that can be done is to remove to the driest pastures. Give corn where possible, and an allowance of common salt in the food.'

To those who desire to learn more of this parasite, I refer them to the latest edition of Professor Williams's *Principles and Practice of Veterinary Medicine*, where they will find it very fully described. I am glad to find such an eminent authority corroborating what I have often ventured to affirm respecting the application of salt to the land.

A few years ago, when sojourning for a short time on the shores of the Solway Firth, I observed a lot of sheep grazing on low-lying land, which at the flow of the tide was partly covered by the sea. I noticed the sheep kept close to the water as the tide receded. I was informed by the shepherd who tended them that they were there as regularly as the tide ebbed and flowed. Instinctively they discovered that drinking the sea water left in hollow places was for their benefit, and that when the tide troubled the waters they found that they proved to them veritable modern pools of Bethesda. Incidents such as that point very conclusively to the absolute necessity of animals having free access to a liberal allowance of salt. From what I have said, I do not wish you to infer that I consider common salt to be a panacea for every ill that animals are liable to. But I would just repeat what I have already said,

that if tracks of rank, coarse, indigestible herbage were periodically burned, and from 6 to 8 cwt. of crushed rock salt sown upon the surface, the loss from parasitic, ay, and other diseases, would be remarkably small. I am one of those who believe that notwithstanding the very best agricultural management and the most enlightened veterinary advice and treatment, that disease and epidemics of disease, like the poor, shall never entirely cease out of the land. But the working of the Contagious Diseases (Animals) Act, with all its imperfections, goes to prove that much can be done by human measures and human means to arrest their ravages, if not entirely to stamp out their periodic visitations.—*North British Agriculturist.*

DAIRY FARMING ON THE CONTINENT.

THROUGH the aid of landowners and others in the district, the **Bithwell Farmers' Club** were enabled to send a deputation to the **Centennial** to report on the systems of dairying practised there ; and the following long but interesting paper was read before the **Club** the other night as the result of their mission :—

In accordance with the decision of the Club, your deputation started on Thursday, the 18th of June last, and proceeded via Leit in the good ship *Thorsa* for Copenhagen. Our course across the German Ocean was almost due east to the southern end of Norway, which we reached early on Saturday morning, calling at Christiansand, where we were allowed an hour ashore. We took a short walk, and were rather struck to find almost the whole buildings erected with wood, tidily kept however, and neatly and tastefully painted. We saw little to interest us from the agricultural point of view, the crops showing evidence of lateness, and would probably require to be cut before being properly ripened. The trade of the port seems to consist chiefly in exporting timber and fish. After a short stay we proceeded on our way, reaching Elsinore, of historic interest, about midnight on Saturday, and Copenhagen early on Sunday morning. When we came on deck, we found the ship hands busy discharging cargo, and the custom-house officials looking upon us with suspicion until our baggage had been turned over to their satisfaction. Traffic seemed to be proceeding in the city very much as on ordinary week days, the shops and offices being open. Having an introduction from Mr. Jenkins, of the Royal Agricultural Society of England, to Mr. Segelcke, Professor of Dairying in the Royal Veterinary and Agricultural College at Copenhagen, we waited upon him, and had a most interesting interview, as to the objects we had in view, and generally on the present state of agriculture in Denmark. Unlike this district of Scotland, where mining and reamaking take the first rank in our industries; agriculture in Denmark is the chief and almost only pursuit of the people, and, therefore, more encouragement is given by Government towards the promotion of scientific knowledge in regard to it.

We were informed that for fully twenty-five years Professor Segelcke had had a stiff battle to fight to bring about the present advanced state of dairying. His first aim was to interest the farmers themselves in the operations of dairying, remove the prejudice of their wives and daughters, and finally to obtain for as many as possible a scientific education, and thus combine 'practice with science.' His aims were at first looked upon as visionary, but by steady perseverance he has been able to show the supreme importance of a scientific education for successful farming.

The great bulk of the land in Denmark is held by peasant proprietors, their average holdings carrying only about six milk cows. It seems a large proportion of these proprietors have to meet a considerable rent in the way of interest on mortgages, and they complain loudly of local burdens. It was interesting, however, to find that from some of these small farms young men, after having spent a few years at the general round of practical farm work, went up to Copenhagen, and, like many noted men in our own country, obtained a scientific education with frugal fare; and we were informed of a case where a student, during recess, did not disdain to eke out a living by taking navy work, and others accepting such situations as might open up to them.

Through the kindness of Professor Segeleke we obtained an introduction to Mrs. Hannah Neilsen of Havartigaard, a farm of 170 acres, about 14 miles north-east of Copenhagen, and having arranged for an interpreter, we drove early on the following morning to her farm. On the outskirts of the town we found considerable areas devoted to market gardening. The absence of fences and the extensive cultivation of rye naturally soon arrested our attention. Considerable areas of clover and sown grasses were also noticeable; in some cases it was being cut green for the cows in the steadings, and in others being pastured in the way peculiar to the country, viz., by tethering the

cows in a row, with spaces between each other of 30 feet, each animal having a 15-foot tether. It was interesting to notice the long rows of cows, and also horses, grazing in this way, and the system has the appearance of being an economical way of pasturing, the animals being regularly watered from carts and shifted to fresh pasture as required. The road to the farm is a fair specimen of a good country side road, and the homestead is an enclosed one with a comfortable and substantial appearance. It is wholly roofed with a thatch of strong reeds. The entrance is by a large close door, through a covered passage, opening into a central yard. The dwelling-house of two storeys and sunk flat occupies the west side of the courtyard, the sunk flat being used as the milk room, churning room, scullery and kitchen, and servants' apartments; the south range contains chiefly the stable of 8 stalls and single cows' byre of 23 stalls; the east range consists of goats' house, root house and byres for young stock; and the north range is taken up with the barn and straw house, and some apartments in connection with the dwelling-house. In outside ranges we found an ice house, and accommodation for young stock and poultry. The milk house, from its low level, can easily be kept cool. The horses and milk cows are found under the same roof, facing each other, with a feeding passage along the centre. The stable stalls, 8 in number, are too narrow for the comfortable rest of the horses, and the cows are apt to foul their stalls by pushing their heads over their feeding troughs into the feeding passage. On a farm in Belgium, we noticed an experiment being tried to obviate this by erecting a spurred frame hung on pulleys with a back balance. Along the heads of the cows is one long trough, without divisions, formed of red brick into a semi-circular shape about 12 inches diameter, and there is a crane at the one end for supplying water for drinking and cleansing purposes. Our own arrangement of glazed fire clay troughs now generally used is we think, a better one. The water for the standing is from a well in the back courtyard, supplied we were told from springs, and pumped up to cisterns by horse-power; but its situation in close proximity to the dunghheap aroused in our minds the strong suspicion that contamination would take place. We found Mrs. Neilson, a very good specimen of a farmer's wife. We arrived at the standing at 4.45 in the morning, and found the dairy operations, in which she took an active part with her staff of eight dairy pupils, in full swing at that hour. She was most courteous, and willing to communicate any information that we wanted, and it was very interesting to be told that amongst her scholars were young ladies of good families, going through the practical detail and regular routine of the dairy work. Two of her pupils had been taken to some place near Edinburgh as teachers, but she complained of the treatment they had received; whilst the labours of one who was at Dunstaffnage Castle at that time, seemed to be much appreciated. Each cow's milk by itself was weighed as brought in, and we found an accurate statement of the yield per annum of the different animals and of the income derived from their produce. All the milk, as soon as weighed, is taken down into the milk room, and there cooled by what is known as the Swartz system. On the floor stand three long tanks, built of brick and cement, about 2½ feet deep by 2 feet wide, with water running in at one end and a plentiful supply of ice to keep down the temperature. The deep narrow tins containing the milk are then placed in the running water, with the result, that the greater part of the cream is extracted from the milk in a shorter space of time than by the ordinary method, and leaves the skim milk available for cheese-making before being tainted. After standing in the water for twelve hours, the cream is carefully taken off, mixed with a little butter-milk to hasten the souring, and stands for about twenty four hours. It is then heated up to 56 or 57 degs. Fahr., and churned in a little upright Holstein churn for fully thirty minutes. Whenever the little granules of butter begin to gather the milk is drained off from the bottom of the churn, and a quantity of clear cold water put in, and the dasher put gently in motion. That water is again let off and renewed till it leaves the butter free of all milky material. It is now taken out and placed in a tub, and turned over with beaters till free of water, when about 3 per cent of salt is mixed with it, and let alone for twelve hours, when it is wrought again, and placed in the wooden pails familiar to you all. By this system 25 lbs. of milk yields 1 lb. of butter. Mrs. Neilson also gave us as her opinion that butter made from whole milk properly ripened is as good as from ripe cream, but it is much more difficult to manage the ripening process. All the produce is retailed from her own shop in Copenhagen, and as the Royal family are supplied with their butter from this farm, it is all stamped with the crown and arms of the King of Denmark, and sold in clean little pots of 1 or 2 lbs. each. Mrs. Neilson has agreed to send through Mr. Speir some of her butter to compete at Kilmarnock next week. She was also doing apparently a good trade in what might be called fancy cheese-making. That morning she had two kinds on hand, viz., Cheddar and Edam. The Edams are the round blue ball like cheeses, we occasionally see in the shops, weighing about 5 lbs. Both kinds were being made much the same as Cheddars are made here; but as she was working on a comparatively small scale, she had not the utensils, nor the conveniences of any of our best cheese dairies at home. None of her cheese did we consider anything extra in quality. She also makes a soft cheese, something like roasted cheese, each about the size of a two-penny pie, and weighing about 1 lb., which she retails at 1s. per lb. She makes more or less of each kind as her customers require them. At the close of our interview we were hospitably entertained by Mrs. Neilson, and shown her various prize medals and certificates, and we left after adding our names to the visitors' book.

About 4 miles to the south we came to the farm of [redacted] owned and farmed by a Danish Vice Consul, who speaks English fluently. The farm consists of about [redacted] acres, and

carries 120 milch cows. The steading is a very large one, with a barn that will hold over 50 tons of straw. The average produce of the cows is 900 gallons a year, and they are realising about 8½d. out of the gallon. We found here the same system of weighing each cow's milk by itself and of keeping only the best cows for milking purposes, and feeding off the others; but instead of the Swartz system of cooling we had the separator at work, and churning and cheese-making carried on on a large scale. The Danish centrifugal separator is a hollow circular machine, driven at the rate of about 300 revolutions per minute, into which the milk is run. The skim milk, from its greater weight, is thrown to the outside of the circle and there taken off, whilst the cream is caught as it gathers in the centre. By this system, within an hour of being milked, the cream may be separated, leaving in the skim milk a less percentage of butter fat than by any other known process. We found here that the cream of 25 lbs of milk yielded 1 lb. of butter and that 14 lbs. of skim milk gave 1 lb. of cheese. The average prices realised were as follow:—Sweet milk 6d. per gallon; butter, 1s. per lb.; cheese, 2½d. per lb. Dairymaids were in receipt of about £4-6s in the half-year and, as at Mrs. Neilson's they presented a clean, tidy appearance, with white caps, coloured frocks and oiled water proof aprons suspended from the shoulders. The greater part of the farm was in crop or hay, 26 horses being used on it. The rotation was something like our four-shift, but no pasture existing a large breadth was in green rye and vetches. To pay the purchase cost, the owner valued his farm at 35s. per acre if leased. There were 8s. 6d. per acre of taxes on the place which included everything.

On returning to Copenhagen we took the steamer in the afternoon to Malmö, a town of some importance in the south of Sweden, where we found the same system of agriculture, good soil, and heavy crops. On Tuesday morning we left Copenhagen for Roskilde, a town about 30 miles to the south-west. The country we passed through was undulating, the heights being sandy, and low places peat or marshy; but most of the land good, and bearing heavy crops. As at home, schellach was a great pest, polluting almost every outfield, and some of them very badly. We visited a Mr. Nilson's farm outside the town, which he rents from a convent at 38s. 6d. an acre. His 26 cows were crossed from the Angeln and Jutland, two native breeds resembling our Ayreshires and shorthorns in their adaptations, but rather larger. They are never outside grazing except for a month or two in the autumn, and the following will show the high feeding practised here, with its results:—In winter the daily mixture for each cow is—5 lbs. bran, 2 lbs. ground oats and barley, 1½ lbs. rape cake, 1½ lbs. palm nut cake, 1 lb. cotton cake, ½ lb. lised cake, 1 lb. earth nut cake, 80 lbs. mangolds, 8 lbs. of hay; and all given cold, as they consider warm food very wearing on the cow. In summer it is 2 lbs. bran, 1½ lbs. cotton cake, 1½ lbs. palm nut cake, with as much clover or vetches as they will consume. The average annual yield of milk per cow is 900 gallons. Each cow's produce is marked down on a board, and when they do not give 750 gallons the owner feeds them off. All the dairy buildings are sunk under the dwelling-house, and are very suitable and clean. The byre had four rows across, with the heads to each other; but the roof was too low, and ventilation very bad. The foot walks were formed of round causeway stones, and were rather narrow and dirty, and precautions against sewage filtration were insufficient; but all the crops on this farm were good and clean.

From Roskilde we drove out 6 miles to an agricultural school at Tune, and found one of the most interesting sights we had witnessed since leaving home. There are five teachers connected with it, receiving from £33 to 112 a year. It possesses endowments of some land attached, and rents some more. A large quantity of milk is bought from the neighbouring farms and converted into butter and cheese. The students average about 50 during the summer, and 100 during the winter months, but before they can be admitted, must have at least two years' working experience on some farm. Your deputation were very much impressed with the appearance of these young men, from seventeen to twenty-one years of age, and mostly drawn from the class of smaller farmers. As we came they had just risen from that day's lesson on Stilton, Cheddar, and Parmesan cheese-making, and were anxious to learn from us something of that, to them, wonderful country, Scotland. They pay a fee of nearly £2 a month for board, lodging, and education, their term being two sessions of nine months each. The effect of these young men leaving this school to superintend the management of their own farms must be of great consequence to the surrounding district. We found the system of book-keeping very complete, a large black board being kept in the milk-room, with the quantities and products of the different farmers' milk marked in separate columns. They pay the farmer the average price of 1 lb. of butter for every 27 lbs. of pure milk, the average price of their butter per English lb. being 1s. 1½d., and their skim milk yielding them about 2d. per gallon when made into cheese. Our attention was drawn here to the manure pit, which was abutting on the byres, the bottom and sides of which were thoroughly cemented, the liquid manure being led a short distance to a circular tank detached from the offices, roofed, and also thoroughly cemented. From the high feeding which is the rule here, the liquid manure is much valued, and is carefully collected and applied to the land in the spring, or during wet weather in summer or autumn. The Danes, but more especially the Flemings, have been long and justly famed for the care which they bestow on this department of agriculture. On the way back to Roskilde we called in at a smaller factory, managed, it seemed, by a man, his wife, and a servant. We found the same system of book-keeping, got the average prices for the same months of the year 1884, which the husband, although a dairyman, could turn over the leaves of his

were also impressed when the good lady of the house turned to our interpreter, and asked us, through him, not to go back to Scotland and make all our own butter, as they still wish to have us as customers.

Having thus explored the district so far round Copenhagen, we parted with the interpreter, kindly granted us by James Gælle & Co.'s agent, and came on across the Island of Zealand to Korsør, stayed there over a night, whence we started next morning at seven, crossed the Island of Funen to Fredericia, then down through the now German Provinces of Schleswig and Holstein, and reached Hamburg about 9.30 p.m. As a whole, there is a sameness about all the land of Denmark; but through Schleswig and Holstein, along our route, was some very poor peat and sand land. Finding no inducement to remain at Hamburg over the night, we left with the 11 p.m. train for The Hague. Almost all the way the land is very flat, even a low hill being seldom seen, and in about thirty hours' travelling we only passed through one short tunnel. Between Utrecht and Amsterdam, the best land for pasture or cropping we had yet seen was passed through, many miles being entirely devoted to pasture or hay. In Holland Proper it was much the same, as all the land is only about 18 inches above water level and under sea level. Small canals go up between each field, with larger ones at the bottom, no fences being used. Cows are never brought in during the summer, all milking being done in the field, a one-legged stool with a handle being used. The crops of hay were very heavy, as one might have expected from the great amount of heat, and the water so close to their roots. A great deal of the hay appears, however, to be rather coarse in quality. The whole country seemed to be what one would call a *beau idéal* one for growing Timothy pure crops of which we did not see, although it was sown. Hay was being taken in in boats, and manure out, canals being used for everything. Market gardening was very common. Having arrived at The Hague at 3 o'clock, we went out to visit a Mr. Waldeck, to whom we had an introduction. He has a large stretch of pure white drift sand, and as sand is used on floors on the Continent, he sells it at a low rate, and gets the land, reclaimed at the rate of 2½ acres per year. Land thus reclaimed is free of all taxes for 20 years, and we were told that the crops realised £25 per acre. We are informed here that any poor in the town or neighbourhood were all supported by the Church by voluntary contribution, and when a severe winter occurred greater liberality was looked for, as a matter of course. In this neighbourhood the spell which had held us of the beauty and romance of the canal system was completely broken. The amount of garbage floating on the stagnant surface; the dark, spongy character of the water; and the pungent odours, which did not soothe the olfactory nerves, made us feel that although the district was a rich one, it was not a very enviable one for the spending of a holiday, and the wonder to us was that epidemics did not more frequently prevail.

We started at three o'clock next morning to see a dairy farm of 107 acres, called Jacoba Hoeve. We were informed that this was a rented farm, and the tenant seemed at first scarcely equal in intelligence to the average farmer in our district, farming 100 acres, although he improved upon further acquaintance. The steading here was certainly above the average of those we had been visiting. The byre was a double one with a centre feeding passage 5 feet wide. The stable was also commodious, having good wide stalls, fair ventilation, and we noticed in front of the horses' heads glazed tiles between the manger and head. A novelty of the piggery was a somewhat rude but effectual contrivance to enable each pig to have its own share of the feeding trough. The water provision we thought rather defective, the well being sunk in the churning room, with only a partition separating it from the byre. We, however, saw a cheap style of water cistern in the corner of the churning room, built of common brick and cemented, and another of the same kind in the pig house for storing feeding stuffs. The milk room was in a sunk flat, and had plenty of water to keep it cool. The milk was cooled on the Swartz system, and the cream ripened and churned, but the quality of the butter, in our opinion, was not first-class. The Dutch system of having their milk vessels painted both inside and outside in strong shades of blue was here noticeable, but we thought our own system of scalding and scrubbing a preferable one. The rent here was about 63s. 4d. an acre, and the farmer appeared to be in fair circumstances, and living in simple style, with his cabriolet to drive his family to church. Having got through Mr. Waldeck, an introduction to a very large farmer at Gonda, we broke our journey there, and drove out, only to be disappointed, as the one young man who, we were informed, had good English was from home, and we could only look on without being able to question; so we hurried back to catch the train for Rotterdam, which we reached at 3 p.m. We found it a very busy town, with much shipping, and some handsome streets and buildings, and, like most other continental towns we passed, we observed in the neighbourhood a large extent of vegetable and fruit farming. From Rotterdam we pushed on to Antwerp, and found quarters in the centre of the city; and considering the flights of stairs we ascended, all of wood, and the bewildering passages we had to perambulate, the thought could not help crossing our minds that if fire did reach us, our only exit would be by the roof. The International Exhibition, like most similar enterprises, was not near completion, although it had been open to the public for some time. In the course of a hurried run through it we noticed the model of a Manitoba Farm, the plans of the Suez and Panama Canals, with sketches of the dredging machinery, and an interesting collection of natural grasses grown there and here. We also saw a very large tree which was discovered last year in the bed of the Rhone, 26 feet in length and 27 feet in circumference at the base, with a gradual taper, and supposed to be 20 centuries old.—*North British Agriculturist.*

DR. AITKEN ON THE DISEASES OF FARM STOCK AND EDUCATION.

THE opening address of the winter session of Royal (Dick's) Veterinary College, as we briefly noticed the other week, was delivered by Dr. A. P. Aitken, Chemist to the Highland and Agricultural Society. Dealing with the above subject, the Doctor said:—There is one direction in which, at this time, veterinary scientists are engaged in work of the highest class. I refer to the study of the infectious diseases of animals. The epidemics, or, I should rather say, the epizootics to which our cattle are liable afford a splendid field for investigation, and one whose utility is not confined to the important one of protecting the agricultural interests and the securing of wholesome food for the people, but it has also important bearings on the cure and prevention of like disorders in the human species.

We are all familiar with the means at present used to rid us of pleuro-pneumonia, and such like plagues. It is the rough-and-ready one of 'stamping out,'—a process which is quite effective to prevent the spread of disease, but it is not one which does any credit to our medical skill. I hope the time is near when something more scientific than the wholesale slaughter and burial of healthy herds may be discovered to rid us of such plagues. In the successful combatting with pleuro-pneumonia we may hope to find a clue to measures which might be available for checking the spread of cholera and other epidemics to which men are liable. It is to you whom we must look, with the increased educational advantages which you enjoy, to extend more and more the domain of medical science in directions in which your practice affords you unusual facilities.

I have alluded to the health of farm stock, and that is a subject with which a large number of our veterinary surgeons in the country are chiefly engaged. When we consider that the number of live stock in these islands outnumbers the people, we see how great a field there is for the exercise of veterinary skill. A very large proportion of these consists of sheep whose diseases are usually treated by the shepherds on the hills, and as the result of this withdrawal of sheep from the care of the veterinary surgeon, the diseases to which sheep are liable are not, in many cases, very well understood.

The circumstances of their lives—usually far away on the hills—and the rapidly fatal character of some of their diseases, set obstacles in the way of investigation, so that veterinary surgeons cannot see and study their diseases, and we frequently hear of farmers losing the half of their stock of lambs without calling in any veterinary aid.

It is therefore much to be desired that farmers themselves should be possessed of some knowledge of veterinary science, for until they are able to watch intelligently the symptoms and development of disease in their hill stock, and until they are able to use with precision some remedies, it does not seem that any material advance in the investigation and understanding of these diseases will be made.

It is also desirable that veterinary surgeons should be instructed in the rudiments of agricultural science, so that they may be in a position to instruct farmers in the care of their flocks and herds, with greater authority, and with more special application to their wants and circumstances. The fortunes of a large proportion of the veterinary surgeons of this country are intimately bound up with those of agriculture, so that anything which affects the prosperity of agriculture cannot be indifferent to the veterinary profession.

At the present time, as you are all too well aware, the agriculture of this country is in a very depressed condition—the depression has lasted long, and even the most sanguine are unable to say that we have seen the worst of it. The causes of that depression are many and complicated, and by no means perfectly understood. They are, in large measure, the same as those which are producing the widespread general commercial depression that is weighing heavily upon almost all branches of industry at this time, for agricultural prosperity rises and falls in sympathy with commerce. Some of these causes, such as inclement seasons, are only temporary; while others, such as increased foreign competition, are permanent; and the natural result of human progress. It is with the latter only that we have to deal. It is vain to hope—it would be folly to expect—that by any fiscal obstructive enactments we can do anything to protect our agriculture from the operation of those causes which are the outcome of scientific progress—that progress which has within the last few years enabled us to lay our hands upon the ends of the earth. We must expect that the facilities for transit, that have so marvellously increased of late, will go on increasing; and that we shall in the future, even more than in the present, have to compete with the industry and enterprise of those who are engaged in producing the world's food in climes more favoured than our own. In order to maintain a prosperous agriculture against permanent forces, such as these, we must bring to bear upon it the operation of forces which are equally permanent and progressive, and there is no force with which I am acquainted that can be employed to protect, to maintain, and to advance our agriculture, but the great power of education. The superior education of our farmers, and of all who are engaged in the cultivation of our soil and the manufacture of our farm products, must form the bulwark of our agriculture.

It must be confessed that as a nation we have been very remiss in this matter. We have left the special education of our farmers almost entirely uncared for. Private enterprise has been allowed to perform, on a comparatively small scale, the work which ought to have been the duty of the State, and we are only now awaking to a sense of the national importance of this matter when we see other nations outstripping in the race in

which we in this country, and specially in Scotland, held the foremost place. The world-wide reputation which Scottish farming enjoyed, we owed to the good elementary education and intelligence of our people, and in great measure to the fostering care of the Highland and Agricultural Society, whose manifold exertions for the good of agriculturists have laid the Scottish people under the deepest obligations. But when we consider that a successful agriculture lies at the foundation of our national prosperity, it is evident that the special education and training of our farmers is too important a matter to be left to private enterprise, or to the limited resources of an agricultural society. We see the nations of the Continent and the States of America making agricultural education a large national concern, and we see them organising agricultural colleges and schools by hundreds, and endowing them liberally from the national exchequer, and the result is that agriculture is rapidly rising from the position of an art to that of a far-reaching science; and there is nothing more certain than that, if we are to hold our place worthily among the agricultural nations of the world, we must follow that example—the prosperity of our agriculture must have its foundations laid in our schools.

I have said that the veterinary profession is intimately concerned in the prosperity of agriculture. Foreign nations have recognised that, and they go further than that, and regard veterinary science as a branch of agricultural education, and their great agricultural institutes and colleges, some of which have a revenue of from £5,000 to £10,000 a year, have a thoroughly equipped veterinary school as a part of their organisation. We have nothing to show in this country which can compare with these things. A few years ago the subject of agriculture was included by the Science and Art Department as a branch of education, in which a capitation grant could be obtained, and a small beginning has thus been made towards the encouragement of agricultural education in the elementary schools; but that is only a small beginning. The higher education of our farmers is still uncared for, and left to private enterprise. Let us hope that this matter, so important for our national prosperity, will ere long receive the attention which it deserves. It behoves all who are interested in agriculture—and who is not?—to use their influence to press the subject of agricultural education upon the attention of our Legislature. We hear at present of many schemes for the improvement of the condition of our agriculturists. Some of these have for their object the simplifying of the process of the transfer of land, and the removal of antiquated laws and restrictions which impede the farmer in the cultivation of the soil; these are much-needed reforms, and if gone about prudently and wisely, they will be productive of much good. And we hear of other schemes—foolish schemes—utopian dreams of agrarian reform which have for their object the multiplication of miserable crofts—little patches of land on which an unlimited number of peasants, with neither capital nor the resources of modern invention to aid them, may spend their energies in the vain attempt to compete with science and capital, and so multiply a race of agricultural paupers.

That is the opposite of all that we want—that is backsliding, and not progress. What we want is education—that education which will teach the husbandman what are nature's laws, and guide him to the most economical and productive expenditure of his energies and his resources, and prevent his engaging in an unprofitable course of husbandry.

Let us hope that that end will soon be achieved, but while we are hoping, let us not be idle. We must not stand waiting upon the 'law's delay.' Each one must do what he can to make for progress in his own way, and according to his ability.—*North British Agriculturist.*

SORGHUM.

DIFFUSION PROVING A SUCCESS.

We have already referred to the interest felt in the outcome of the experiments on a working scale in extracting the sugar from the sorghum cane in Kansas, and the ribbon cane in Louisiana by the diffusion process, under the auspices of the Department of Agriculture. The results of these experiments, we said, would demonstrate whether at present prices sugar can profitably be made from the sorghum cane. And they are no less important as regards the sugar cane of the south, since the loss of sugar in milling the cane has been fully as great as in case of sorghum cane at the north. The following letter to the *Rural World* will be read with interest, giving as it does good ground for the belief that the problem is now being successfully worked out in the works of the Franklin Sugar Co., at Ottawa, Kan., by Prof. Wiley, of the department, and his associates:

"I regard the results obtained here as decisive of the northern cane business. The present system of manufacturing cane has brought out in bold relief the difficulties which must be overcome before success can be attained. Low prices and the sharp competition of other products drive us to the use of more economical methods of extracting and better methods of clarifying the juice. Necessity compels the manufacturer to avoid the extraordinary loss caused by rolling cane. The department of agriculture recognizes this fact, and has tested the diffusion process on northern cane on a practical working scale with extraordinary success.

"The Franklin Sugar Co., at Ottawa, Kansas, have immense double mills with rolls closely set, driven by a 150 horse power engine which labors hard producing as dry bagasse as is possible by that method. I was told the cost of the mills, and

boilers of the grinding apparatus alone, was about \$20,000. The mills are speeded to extreme slowness to obtain the largest possible per cent of juice, and yet there is a loss of over 40 per cent of the sugar remaining in the bagasse.

"Saving this large loss means a margin of profit to the manufacturer, and it means the success of the cane business. The diffusion experiment is an effort to save this loss, and it is a successful effort.

"The diffusion apparatus consists of cutters revolving at 220 revolutions per minute, which cut the cane into ten diffusing cells or tanks. The knives are grooved so that the cane chips have no flat surfaces to lie close together, preventing free flow of liquid through the mass. They were designed by Dr. Wiley, and do the work perfectly. One cutter is used, while another is sharpened. The knives are used four or five hours before sharpening. The only difficulty in the experiment has been in the faulty shape of the diffusing cells. A battery built for beet pulp is not suitable for cane chips, because the chips frequently pack in the cells and cannot be readily removed. This can be easily remedied by altering the form of the cells and enlarging the outlets. Dr. Wiley says diffusion is as easily applied to northern cane, and gives as good results as in best manufacture.

"The battery consists of ten cells, each of these cells holds 1,340 pounds of cane chips, they should hold one ton each. A cell is filled with cane chips and then with warm water, this water is after a short time drawn into the next cell which is also full of cane chips, and so on until all the cells are filled. The first cell has by this time lost all sugar and is emptied, and this process goes continually on, eight cells being always under pressure, and one being filled and one being discharged.

"On October 8, the diffusion battery was operated eighteen and three-fourth hours, the number of diffusions was sixty-seven, the average time of each diffusion was seventeen minutes, the amount of cane in each cell was 1,340 pounds, the total weight of cane diffused was 89,730 pounds, the weight of juice obtained was 95,920 pounds. The extraction of sugar was surprisingly perfect, only traces of sugar were found in the exhausted chips and in the waste water, amounting in all to three-tenths of one per cent of sugar lost. The diffusion juice average ten per cent of total solids, of which six per cent was sucrose, two per cent glucose, and two per cent solids, not sugar. The total weight of coal used from 6-30 A.M., October 8, to 6 A.M., October 9, was 3,276. This gave the steam used for driving the apparatus and for heating the liquid in the diffusers. The weight of coal used in working a ton of cane was sixty-five pounds, worth here ten cents.

"Four men were employed on the cane carrier by day and four by night, at \$1.25 each—\$10.00; four men operated the diffusers by day and four by night at \$1.25 each—\$10; two firemen at \$1.50 each—\$3.00; one boy at 75 cents—75 cents, costing in all \$28.75, or 57 cents per ton of cane worked. There were annoying delays caused by the faulty shape of the cells, and with a battery properly constructed it would cost no more to diffuse 150 tons of cane in the same working time.

"Prof. Swenson, the superintendent of the Franklin Sugar Works, and Mr. Parkinson, the managing director, whose opinion I value because they have had the largest practical experience in working cane, both unhesitatingly say that diffusion is a success. They want no more mills; they say diffusion juice is more easily defecated. It costs less for power and for apparatus, there is less danger of breaking the machinery, that nightmare of the cane business, and a break would be much less serious than a break in a cane mill. The application of diffusion to northern cane is a left stride ahead.

"Diffusion is not the only successful experiment which has been tested by the Department of Agriculture. Carbonatation is a brilliant success. The diffusion juice is mixed with about one and a half per cent of lime, it is then run into a tank containing a steam coil and also a perforated pipe, which is connected with a lime kiln by an air pump. Carbonic acid gas, produced by heating lime stone, is forced through the juice, until the lime which was added to the juice is converted into the carbonate of lime, which rapidly settles and brings the impurities to the bottom. It was wonderful to see the effect of this process, the juice becomes limpid and sparkling and has just the right tinge of color. I saw carbonated juice, and the same juice uncarbonated boiled in an open pan to syrup, side by side; there was money and satisfaction in the carbonated product, there was neither in the other. Carbonatation so purifies and cleanses the juice that heat has less injurious effect. I heard the manager of the sugar company say that the process was worth \$100 a day to the company. I heard the superintendent of the sugar company say, "Now there is money and pleasure in the business." I heard Prof. Hart, the assistant superintendent, say, "It saves the 20 per cent loss usual in skimming and waste, to say nothing of the quality of the product." I heard a Chicago capitalist, who is looking for a location for a sugar factory, say, "Diffusion saves 41 to 50 per cent of the juice. Carbonatation saves 20 per cent of the loss in waste, and increases the value of the product. I can make sugar without any tariff." I heard employees of the sugar company say, "It is fun now to work extra time, for we are making good goods and money for the company." I send you a sample of the precipitate from the carbonated juice, the latter contains all the impurities removed from the juice, and as it can be washed there is no loss, as is the case in skimming.

"This experiment has been made with the cheapest and rudest apparatus, but it has been tested on a large working scale and there is no part of sugar manufacture more worthy of further trial. If some modification of this process can be adapted to smaller factories, there will be an advance all along the line, and the northern cane business will immensely improve the quality and immensely increase the quantity of its products.

Mr. J. S. Spencer, who has studied the process in beet factories and who, I am told, was sent by the Department to Europe and had charge of this experiment.

"It should be remembered that there is nothing new, nothing empirical about diffusion of carbonatation, both have been used in the beet business for many years. These processes are simply transferred from one industry to another, and the Department of Agriculture has demonstrated their adaptability to northern cane, not only by laboratory experiments, but also by satisfactory tests on a large scale, and the much less room for doubt than if they were new discoveries.

"The Department of Agriculture deserves the thanks of the cane growers and manufacturers and of the country. It has rescued a struggling business, and the results will benefit the country. In all this western country cane is easily produced in any quantity. The success of cane depends on using proper methods of manufacture, and by expensive experiment the department has improved the methods.

"Dr. Wiley has been ably seconded in the work here by his assistants, Messrs. Richardson, Spencer and Dugan; of the division of chemistry of the Department of Agriculture, Washington, D. C., and also by Prof. Scovell, and by Mr. Foreythe.

"All have shown enthusiasm and energy and disregard of extra or night work and anxiety for results. I have seen the manager of the sugar works carrying cane to the diffusion cane carrier at midnight, when help was wanted, and heaving limestone into the lime kiln and enquiring everybody.

"I am told Dr. Wiley is a graduate of medicine, an accomplished musician, an able journalist and chemist. He seems also to be a mechanic; an engineer, and to have a good executive ability, and yet he is scarcely forty. I asked him why he was and old bachelor, and he said it was because his girl said, "Pass those molasses please." I am always asking foolish questions, and sometimes I do not get correct answers. I nervously retract all I have said about 'heterodoxy,' and 'archæology' because he is saving sorghum. Good work has been done and good results have been obtained at Ottawa.—A. A. DENTON, —Farmers' Review.

LAND UNDER TEA IN ASSAM.

LAST year there were only 15 applications under the Waste Land Rules of 1876 for land required for tea cultivation in Assam, which shows a considerable falling off as compared with previous years. It must however, be remembered that a very large number of the applications generally come to nothing. In fact, the area granted last year on 13 out of the 15 applications was 3,103 acres, as compared with 2,045 acres on eleven grants in the previous year. Altogether, excluding grants resumed and resigned, there are at present in the Assam Valley 475 grants under the above rules, covering 167,683 acres, and paying land revenue amounting to Rs. 43,546. More than one-fourth of this acreage is in the Nagaong district, but lately the applications for land have become more numerous in Darrang, Sibsagar, and Lakhimpur. Under recent orders issued by Mr. Elliott, applications for waste land under the rules of 1876 must now be limited to 600 acres whereas the former limit was 1,500 acres. Waste land for tea cultivation is also still taken up under the ordinary Assam Settlement rules, and last year 193 decennial and 23 annual leases, covering a total area of 20,298 acres, and paying a revenue of Rs. 15,529, were issued. It appears, however, that it is contrary to the standing orders to issue annual leases to tea planters, but the Commissioner of the Assam Valley explains that much leases still continue to be issued, because there has been some difficulty in getting the lands applied for surveyed, and that such annual leases will be converted into decennial leases when the lands have been properly surveyed and boundary marks have been erected. This excuse does not satisfy that Chief Commissioner, who is of opinion that there should be no greater difficulty in getting lands surveyed under the Assam Settlement rules than there is in the case of lands applied for under the rules of 1876. It has, therefore, been decided that the issue of annual leases to tea planters must cease altogether, and applications for lands for tea under the Settlement rules must be treated as pending until the land has been actually surveyed and the decennial lease issued. The planters would, therefore, do well to bear in mind that an essential difference exists between an annual and decennial lease, or when the land revenue regulation comes into force, he may find that an annual lease confers upon him no valuable property in the land he occupies. Altogether there existed at the close of the year, in the Assam valley, 542 decennial and 200 annual leases, covering a total area of 76,937 acres, and paying Rs. 1,18,665 as revenue. This gives an increase of 19,160 acres of land granted for tea cultivation since the year 1881-82; and shows that, notwithstanding adverse circumstances, steady progress is still being made in the demand for tea land. Up to the close of last year there were in existence altogether 1,853 grants or leases, covering 5,09,051 acres, issued under the different Waste Land Rules that have from time to time been in force in the province, and also under the ordinary Assam Settlement rules. Of this acreage the largest area, 3,33,008 acres, is held under the redeemed old rule grants or in fee simple.—*Englishman*.

HOLLOWAY'S PILLS.—Epidemic Diseases.—The alarming increase of deaths from cholera and diarrhoea should be a warning to every one to subdue at once any irregularity tending towards disease. Holloway's Pills should now be in every household to rectify all impure states of the blood, to remedy weakness, and to overcome impaired general health. Nothing can be simpler than the instruction for taking this corrective medicine, nothing more efficient than its cleansing powers, nothing more harmless than its vegetable ingredients. Holloway's is the best physic during the summer season, when decaying fruits and unwholesome vegetables are frequently deranging the bowels, and daily expiating thousands, through their negligence in permitting diarrhoeal action, to the dangers of diarrhoea, dysentery, and cholera.

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, DECEMBER 26, 1885.

[No. 52]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 16TH DECEMBER 1885.]

Madras.—General prospects fair; continue favourable in Bellary and Anantapore.

Bombay.—River still low in Sind. Slight rain in most districts of the Deccan and in parts of Bijapore, Belgaum, and Upper Sind Frontier; more wanted for rabi crops in parts of Nasik, Ahmednugger, and Khandesh. Reaping of *kharij* and sowing of rabi crops nearly completed in most districts; standing crops damaged by drought in two talukas of Khandesh, by blight in one taluka of Dharwar, and by blight and insects in parts of Bijapore. Cholera and small-pox in parts of three, cattle-disease in parts of twelve, and fever in parts of fifteen districts.

Bengal.—Rain reported from almost all districts of Behar, and from Dinagepore, Rungpore, Burdwan, and Hazareebagh. In Behar and Hazareebagh it has greatly benefited the rabi and poppy crops. *Aman* harvest is generally yielding a good outturn, except in the parts of South-West Bengal deeply inundated in August and September. Price of rice is generally lower than last year, and it has further fallen in several places during the week with the appearance of new rice in the market. Public health continues generally fair.

N.-W. Provinces and Oudh.—Rain has fallen in all reporting districts but one, and has benefited the rabi greatly. Prospects are good. Supplies are ample and prices generally steady. Public health is good.

Punjab.—Moderate rainfall in a few districts, more wanted. Health generally good. Rabi sowings approaching completion. Prices fluctuating.

Central Provinces.—Rain has fallen and cloudy weather prevails in all districts, except Sumbulpore. Rabi crops improved; *juari* slightly damaged in Nagpore. Fever in parts. Prices steady.

British Burmah.—Cholera slight in five districts, elsewhere public health good; cattle disease slight in eight districts, elsewhere health of cattle good. Crop prospects good in all districts except in Tharrawaddy and Prome, where the crop is fair, and in Thayetmyo, where it is poor.

Assam.—Weather seasonable. Public health fair; cattle-disease in some monzabs. Reaping of *sali* being continued; gathering of *matikalai* and *mugh* in some villages commenced. Crop prospects very fair. Cholera reported in some parts of the district. Common rice 16 seers per rupee; tea season closed.

Mysore and Coorg.—Weather cloudy. Fever prevalent in parts of Bangalore, Tumkur and Shimoga; cattle-disease in parts of Shimoga and Kolar. Standing crops in good condition. No material change in prices. Prospects of season and public health good.

Berar and Hyderabad.—Weather rainy. Rainfall has somewhat injured cotton and *jowari* crops; rabi in good condition; prices in Amraoti—wheat 22, and *jowari* 26 seers per rupee. *Abi* crops prospering; harvesting of *kharij* crops continues in some places. General health of taluka fair; fever has disappeared. Prices in Hyderabad—wheat 14½, coarse rice 12½, white *juar* 20½, yellow *juar* 27½, and *tur* 15½ seers per current sica rupee.

Central India States.—Weather cloudy and cold; and except for a few drops of rain in Indore, there has been none elsewhere. Health good. Prospects of crops much improved. Opium prospects fair. Prices steady.

Rajpootana.—Weather very cloudy; nights frosty. Fever still prevalent. Except in Meywar, Sirohi, Pertabghur, and Kerowil. Tanks and wells fair. Crops average. Small-pox slightly prevalent. Prices stationary. Health and crop prospects good. *Kharij* crops being gathered. Rabi sowings nearly completed. Prices in Pertabghur—wheat 20½, *mukka* 31, and gram 37 seers per rupee. Outturn of *kharij* in Kotah much below average. Fever and a slight small-pox prevalent in Ajmere. Crops germinating in Bhurtpore.

Editorial Notes.

Our readers will remember a short time back the paragraph we published regarding the ensilage experiment carried out at Allahabad during 1884-85. At that time we had only been furnished with a statement showing the number of silos made, the quantity of fodder and grass silaged, and the cost of the experiment. We have now before us an interesting memorandum drawn up by Captain S. C. F. Peile, Assistant Commissary General, embodying the practical results of these experiments. The memorandum, which is of sufficient interest in itself to repay perusal, will be found elsewhere.

**

Up to last week the reports of the brokers stated that the total quantity of indigo out of the market was 50,000 maunds against 38,500 maunds last year. Of the above quantity, about 11,000 maunds were Bengal, 21,700 Tirhoot, 4,500 Benares, and 12,800 Oudh. The demand for good and fine indigos has not been so keen, and the prices for these qualities are quoted from 5 to 10 rupees lower. But on the other hand ordinary to middling have realised fully previous rates: whilst Oudhs generally are rather dearer.

**

We understand that the honorary title of "Commissioner for India" has been conferred by the Royal Commissioners on Mr. E. C. Buck, in recognition of the work performed by the Revenue and Agriculture Department in India in connection with the Indian courts at the forthcoming Colonial and Indian Exhibition. The title is of an honorary character, and carries with it no duties or responsibilities outside India. The statement which we recently made that Mr. Buck proceeds home on furlough and not on duty connected with the Exhibition is therefore, notwithstanding the conferment of the above title, absolutely correct.

**

In October last a proposal was made regarding the desirability of establishing experimental botanical gardens at Gudalur, Kuttalum, Russellkonda, Hospet, Ramandrug, Yercaud, Chittoor and Palmaner in the Madras presidency, and Mr. Lawson, the Director of chinchona plantations, parks and gardens, Nilgerris, was called upon for any remarks he may have to make upon the subject. His report is an interesting one, and will be found elsewhere. The Government of Madras consider, however, that to begin with, it will be sufficient to establish gardens at Gudalur and Kuttalum, under the management of trained overseers. Mr. Lawson has been requested to visit Ramandrug and Yercaud, and to report after inspection in which of these localities he would propose to establish gardens.

**

The same paper has the following remarks on the sugar market:—

The more favourable tone of the foreign market during the last few days has strengthened the tendency of prices, the quotations showing an advance, so that the present aspect of the market is much more favourable than it has been. A further improvement is also expected, since the total production of Europe is, according to the latest calculations, much less than was thought. The deficit in Germany is estimated at 18 per cent, in Austria 40 per cent, in France 25, and in Belgium 33 per cent. According

to these figures the production of Germany is taken at 97 million metercentners, that of Austria 36 millions, and that of the four countries named 19½ million or 5½ million less than in 1884-85. The Zucker-raffinerie Bruunola manufactured during the business year 1884-85 84,900 centners of raw sugar, against 80,633 centners in the preceding year.

.

WRITING on the subject of the jute industry in Germany, *Kuhlow's Trade Journal* says:—

In order to learn with certainty whether over-production prevails in the jute market the manufacturers in this industry have just procured statistics from the Imperial Statistical Office. From January 1st to June 30th, 1885, the imports of unbleached, dyed, and unprinted jute and Manila hemp yarn within the German customs district were 9,986 doublecentners of 100 kg. and those of the bleached, dyed, and printed jute, &c., yarn were 226 doublecentners, together 10,728 doublecentners or 1,072,800 kg. Of jute and Manila hemp stuffs 14,269 d.c. or 1,428,900 kg. were imported. The imports of jute sacks are estimated at 1,693,000 kg. The imports of jute, linen, and hemp yarn up to No. 8 English were up to the end of August 1,211,200 kg., those of jute, linen, and hemp yarn between No. 8 to No. 20, 4,428,400 kg., and of jute and Manila stuffs, as well as linen, ticking, and huckaback up to 16 threads to 4 square centimetres surface 2,190,600 kg. From 17 to 40 threads 894,900 kg., together 3,035,500 kg., or 30,855 doublecentners.

.

THE Melbourne trade returns show symptoms of a healthy revival. During the four weeks ending on the 17th of November, as compared with the corresponding period of 1884, the imports showed an increase in value of £197,554, and the exports of £417,933. The largest increase in imports was in tea, which improved to the extent of £114,298. There was also an increase in the value of sugar, spirits, wine, tobacco, iron, and timber. An increased export of gold more than accounts for the whole increased value of exports; for this is put down at £495,346. On the other hand, there was a large decrease, not only in the value, but in the quantity of wool exported. The total export of gold from the 1st of January to the 14th November this year is valued at £3,768,542, showing an increase of £1,660,446 over the corresponding period of last year. On the other hand, the decrease of the value of merchandise exported during the same time represented £1,846,376.

.

It is satisfactory to note that the exports of tea from Calcutta to Great Britain are steadily increasing. The exports in November amounted to 11,644,612 lbs., the returns for the corresponding months of the two preceding years being respectively 9,390,037 lbs. and 7,140,887 lbs. The total exports from the 1st of May to the end of November were 47,730,072 lbs. The trade with Australia shows an even more remarkable development. Up to the end of November the shipments amounted to 1,384,784 lbs.; the quantity in 1884 being only 577,518 lbs., and that in 1883, 206,536 lbs. There is also an improvement in the trade with America, although the exports to that country (70,946 lbs.) are considerably below those of 1883. Altogether there is an improvement in the trade up to date, as compared with last year, of nearly five million pounds. The Ceylon trade is also advancing with rapid strides, the figures for the past three years (from 1st October to 19th November) being 101,286 lbs., 193,869 lbs. and 471,402 lbs. The exports from India to England include 534,217 lbs. that were lost in the steamers *Indus* and *City of Manchester*.

.

A TELEGRAM from a Madras correspondent of the *Times of India*, dated the 17th instant, states that "an extraordinary advance has taken place in London in the value of the shares of the Mysore mine, due, according to the *Mail*, to the development of a true fissure vein which it is confidently anticipated must continue through the Ooregum, Nundydroog and Balaghat properties, and so large a mass of rich quartz is available that it may take a century to exhaust the yield. The gold in the Mysore mine has averaged four ounces per ton from June last year, when the month's outturn was fifty-two ounces to last month, when the outturn was one thousand and

ninety-six ounces. During the eighteen months the yield has aggregated six thousand and fifty-nine ounces. The present month's yield will be at least as great as November's. The reef has been traced to a depth of 250 feet. The stone increases in richness with the increase of the depth of the mine. Actual transactions have taken place in Ooregum in London at twenty-five shillings. The quotation for *Consolidated* is thirty shillings. There are rumours of negotiations for resuming work on or acquiring blocks of other companies on the field."

.

THE following is the memorandum on the prospects of the cotton crops in the Bombay presidency, for the month of November:—*Sind*—Area sown 56,000 acres, area up to average, but 17,000 acres less than last year; field inspections not complete. *Gujrat*—Weather seasonable; plants flowering. *Native States*—Baroda—Returns incomplete; Kattiawar—area 1,775,000 acres; in other States area 300,000 acres; these figures must be received with caution; average area unknown. *Deccan*—In Khandesh picking in progress; crop patchy but excellent in parts, in others much of the sown area has been re-sown with other crops, rest of Deccan crop less forward. *Bombay*—Karnatic—Season late; east winds have set in, but as yet little damage reported. On the whole the area sown in British districts is 325,000 acres below average and 300,000 acres below last year's area. In Native States, exclusive of Baroda, the area sown is 100,000 acres above last year's area. Total area British districts 1,950,000 acres; Native States, besides Baroda, 2,225,000 acres.

.

THE following is the first report on the prospects of the Wheat Crop in the Bombay presidency:—*Sind*—Returns not received. *Gujrat*—Area everywhere less than last year, except in Surat, and below average except in Broach and Surat; decrease due to insufficiency of late rains; area 250,000 acres, or 100,000 acres less than six years' average, and 125,000 acres less than last year's area; condition of young crops good; slight damage in Broach from cloudy weather in November. *Native States*—Returns incomplete. *Deccan*—Area 950,000 acres, or 125,000 acres above average and 100,000 acres above last year's area; increased area due to rain being unseasonable for early crops; young plants healthy; heavy dews or else showers looked for to bring the crops through, especially in Khandesh and Nasik. *Bombay*—Karnatic—Last year abnormally large and unfruitful area, this year area nearly 400,000 acres or 50,000 acres above average; the increase is merely nominal, because the *jowari* crop was sown more extensively; plants healthy; cold weather has come seasonably. *Native States*—Area 75,000 acres, or about average, though 25,000 acres less than last year's area.

.

It will be remembered by many of our readers that last February a very successful agricultural show was held at Doomraon in the district of Shahabad. With a view to keeping alive and stimulating the interest that was then aroused amongst all classes of the people, the prospectus of a second show in the same district is now announced. The Government of Bengal has sanctioned the contribution of Rs. 2,000 from the divisional Exhibition Fund, and the Director of Agriculture has promised a grant of Rs. 500, while with their usual liberality, the Maharaja of Doomraon and the firm of Messrs. Burrows, Thompson, and Mylne have each subscribed Rs. 500. It has been arranged to hold the show on the 4th March next, simultaneously with the great cattle and horse fair at Barahpore, two miles from Raghunathpore on the East Indian Railway. The committee intend to hold trials of the simplest and most effective improved ploughs, and to establish a depot at the show for the distribution and sale to cultivators of samples of selected seed of staple crops. It is particularly hoped that the hand-

some prizes offered for cattle will tempt breeders to send exhibits from a distance.

We have stated before that the jute mills had at last finally agreed to reduce work to four days per week, the Hooghly Mills alone refusing to become parties to the arrangement. With this one exception, the Mills are we learn unanimous, and the Association has resolved to adopt the measure without further reference to them. However little the Hooghly Mill agents may suspect it, they are moving directly counter to a growing conviction which repudiates the economic theory that was so long permitted to outrage the instincts of the human mind, that self-interest and 'the survival of the fittest' are the last word that political science had to pronounce upon this subject. A truer insight is teaching the leaders of thought everywhere, to repudiate the hateful theory that the controlling principle of every man's relations with his fellows, should be the calm unflinching pursuit of his own interests. There were never wanting those who refused to bow the knees to this Moloch, and the repudiation of its degrading worship is daily eliciting sharper emphasis from the students of social science. It is happily dawning upon political economists themselves, that the simple Christian morality which requires us to "Look not every man upon his own things, but every man also upon the things of others" has somehow or other, the force of natural law upon men's relations with each other everywhere, and that to repudiate it as the older economists have unwisely done, means the eventual destruction of social order and well-being.

We say this because we understand that the agents of the Hooghly Mills state frankly their conviction that the common action in which they are asked to join, is a departure from those principles of political economy upon which the welfare of society depends. They no doubt believe so sincerely, and can readily find corroboration of their view in the economists of the last generation, but political economy is a comparatively new science, and its so called 'principles' are now passing through a crucible, from which the dross is being discarded. Amongst this dross, we find this principle of pure self-interest as the rule of action, unhesitatingly repudiated as economically unsound, as it was ever instinctively felt to be repellent. It is an invidious position for the agents of the Mills to occupy, as they themselves say, and a position they would like to abandon, if but convinced that they would act rightly in doing so. We have no right to ask them to take our verdict upon the matter, but we think we may assure them of this, that they will find no leading writer of the present time supporting the principle which they think themselves bound to vindicate in the public interests, at the cost of much odium to themselves. They would find that there has been a gradual but great change of views on the subject, and that the answer to their enquiry would be that their action is *not* in accordance with modern thought on the subject, but must be regarded as of an order that would prove fatal to society if it were universally adopted.

The following is a summary of the health, crop, and weather reports for the week ending 16th December 1885:—During the week under report rain has fallen generally throughout the Madras presidency, the Berars, the Central Provinces, and the North-Western Provinces and Oudh. Slight rain has also fallen in Mysore and in a few districts in the Panjab, Bombay, Bengal and Assam. From one or two places in Central India and Rajputana slight showers are also reported. The standing crops are generally in good condition in Madras, and those which are being harvested promise an average outturn. In Benary and Anantapore prospects continue favourable. In Mysore and Coorg crops are good. In parts of the Bombay presidency more rain is wanted for the *rabi* crops, the sowing of which has been nearly completed in most districts. The *khari* harvest is nearly over. In the Berars and Hyderabad the *rabi* promises well, and in Central India and Rajputana agricultural prospects are generally good. In the Central Provinces the *rabi* crops have been improved by the recent rain: the *khari* is being threshed in Jubbulpore and Seoni. More rain is still wanted in the

Punjab for the *rabi* crops. In the North-Western Provinces and Oudh the *rabi* crops have been much benefited by the recent rains, and prospects are good. In Bengal the recent rain has greatly benefited the *rabi* and poppy crops in Behar and Hazareebagh; the *amra* harvest is yielding almost a good outturn, except in the inundated tracts. In Assam the prospect of the season continue good. In British Barmah the rice crop is being reaped and promises well in all districts except Tharrawaddy, Prome, and Thaeinayo. The public health is generally good. Prices are fluctuating in the Panjab, and are falling in Coorg. In Bengal the price of rice is lower than last year. Elsewhere prices are fairly stationary.

Horticulture and husbandry at Erfurt, Prussia, seem to be labouring under most unnecessary restrictions imposed by the laws relating to the vine lice. A German contemporary informs us that the Erfurt Chamber of Commerce, in a report upon the wholesale horticultural and general husbandry industry, says that, notwithstanding a good harvest, the results are not so satisfactory as was expected. The causes, it is said, are to be found in very depressed prices, which often did not cover the costs of production, a less sale, and slack trade in general. The fall in prices was chiefly noticeable in the cole seed, carrot seed, green leek seed, early salad, celery, Swedish and autumn turnips, beet-root, radishes, pease, kidney beans, and grass seeds. There was an increase of prices for onions and cucumbers, but the yield was less. There has been a good harvest of most kinds of flower seeds, and only in a few cases is there a falling off, but as a set-off, prices have fallen very low. The plant trade suffers more every year through the restrictions imposed by the laws respecting the vine lice. Gardeners throughout Germany complain bitterly that of all the countries which have joined the Berne convention for combatting the vine louse, Germany is the only one which is less favourably treated by its own authorities than it is by the authorities of other lands. In France, Belgium, and Holland every husbandman can import plants, with the exception of the vine from abroad if they are not condemned by the experts on the frontier, but such plants cannot be sent to Germany without encountering serious difficulties on the frontier. For instance, plants which have come to Germany from Brazil are sent back again, and only with the express sanction of the Government authorities is their importation possible. It is satisfactory to note that the business with all countries—and especially with England and the United States—in dried flowers and grasses is increasing.

Great efforts are being made to have Indian tobacco properly represented at the forthcoming Indo-Colonial Exhibition. There is no doubt that once fairly launched, Indian tobacco will make its own way in the European markets. With regard to the arrangements made by the Government of India, it appears that, before the idea of a separate tobacco room in charge of Messrs. H. S. King and Co., had been mooted, arrangements were being completed to obtain for the section of the Imperial Economic Court devoted to narcotics, a collection of Indian tobacco, raw and manufactured, which would have included commercial or trade samples contributed by Agricultural Departments or offered by private growers and manufacturers. But that when Messrs. H. S. King and Co.'s proposal to have a separate tobacco room was put forward, the Government of India, recognizing the advantages it offered for pushing the Indian tobacco trade, sanctioned it and modified its own arrangements. Messrs. King, Hamilton and Co., of this city, being agents of the London firm will therefore have the entire responsibility of collecting and despatching samples, the Government of India being prepared to render any reasonable assistance in the equipment of the tobacco room by making known their (Messrs. King's) arrangements and requirements through the various local Governments and administrations. We take this opportunity of stating that Messrs. King and Co. will be prepared to take large quantities of tobacco; and in the case of samples suited for European consumption, would be prepared to receive a continuous supply from manufacturers for sale throughout the Exhibition.

In spite of bad trade and greatly reduced profits, the British production of coal shows an increase of 31,000,000 tons, or about 23 per cent in the five years ending 1883, the out-put in the last-named year being nearly 164,000,000 tons. This wonderful progress has been established against the repressing influence of the most severe depression in prices that trade has ever known. That this almost universal depression has not slackened the coal exports from the United Kingdom, is clearly shown by the demand abroad increasing for the British mineral during the years 1884 and 1885. France is England's best customer, taking from our mines something like 4,000,000 tons per annum. Italy follows the Republic with a little under 3,000,000 tons; Germany, on the whole, absorbs nearly the same quantity, while Russia and Northern Europe collectively take considerably over 4,000,000 tons. Spain, Egypt, and India consume each more than a million tons, and we believe that the Indian figure would be fairly represented by 100,000 tons per annum or 1,200,000 a year. The foreign demand for British coal advanced from 11½ millions in 1870 to 14½ millions in 1875; and it is expected to attain 31 millions of tons in the present year, 1885. These are startling figures for those political economists who forecast the final exhaustion of British coal resources. This home consumption is increasing, as well as the foreign export; and to meet these demands, the output must keep pace. We are glad to see that this is not accomplished by an extra drain on the old working, but by new undertakings. Speculation continues to hold good that possibly coal may be found in Kent and Surrey. There can be no doubt that the coal-fields of India, China, Borneo, and Australia, will in the future almost entirely dispense with the necessity for export to meet the requirements of the steamers engaged in British trade in far distant waters; while nearer home, present customers are likely to be independent of extraneous indent, and able to meet their own wants from local or nearer sources of supply.

**

A short time ago we noticed the offer made by the proprietors of the Nilgerri Brewery to purchase locally large quantities of barley if the cultivators (Badagas) would undertake to grow it on the hills. The brewery people were advised by the Madras Government to import the seed from home and distribute it amongst the Badagas, who it was thought would gladly enter into contracts to supply the demand of the brewery. We now learn with satisfaction that with a view to assist the brewery company in procuring grain for malting purposes, the Government of Madras have sanctioned a proposal of the Director of Agriculture and Settlement to procure 80 bushels of barley from England for distribution among the ryots of the Nilgerri district. This is to be treated as an advance made by Government for cultivation, and recovered as an arrear of revenue under section 53 of Act II of 1864 (Madras). Mr. Burrows, the Collector of Nilgerri, in submitting his proposal, stated that he trusted by means of a little wholesome pressure to induce some of the Badagas to take the seed, and the knowledge that they have to pay for it, will probably act as an incentive to more care in cultivation than is usually bestowed on seed given gratuitously for experimental purposes. He added, and very rightly too we think, that the Badagas should not be required to furnish any information about their crop, as this requirement puzzles and frightens them, and makes them regard a supply of seed from Government for experimental cultivation as a pure misfortune; that he himself would keep a watch on the persons who take seed and obtain information as to the results in a general way. In these views the Director of Agriculture entirely concurs, and we agree with him in thinking that if the attempt succeeds, the result will be very much to the benefit of the cultivators, the Brewery Company, and ultimately to that of Government also, as it will tend to cheapen beer. The stake is certainly not likely to be a large one, and we think there is a fair prospect of a gain to all concerned. Mr. Burrows, the Collector of Nilgerri, certainly deserves credit for initiating a new venture in this connection, and we hope that he will not be repelled from the Nilgerri district before he has had opportunity of carrying out his programme.

The weightment of Indian Tea is to undergo modification, and the following circular issued by the Assistant Secretary to the Indian Tea Association, will doubtless be read with interest by those engaged in the Tea industry:—

I am desired by the General Committee to hand you copy of a General Order No. 65 1885, dated the 9th November 1885, which has been issued by the Commissioners of her Majesty's Customs, and which contains revised regulations for ascertaining the weight of Indian Teas on importation into the United Kingdom. The Secretary of the Indian Tea District Association of London, in a Circular issued from his office, says:—"With reference to Clause 2, I desire to draw the special attention of Managers of Tea Estates to the importance of careful bulking and weighing at the Gardens. The satisfactory working of the regulations depends entirely on accuracy in these respects. It is also desirable that the tares of the packages of each break should run as even as possible as any great variation in this respect gives rise to suspicion on the part of the Customs and the Trade, and may lead to the whole of the Teas being turned out." I am to add that information has been asked for as to the nature of the statement required to be given by Importers of Tea under Clause 2 of these revised regulations.

General Order 65, 1885.—Custom House, London, 9th November 1885:—

SIR,—I am desired by the Board to acquaint you that in consequence of representations made to them on behalf of the Indian Tea Trade, they have approved of the following regulations for ascertaining the weight of Indian Teas on importation in lieu of those laid down in General Order 5 1884, which is hereby cancelled, viz:—1. The packages on arrival to be weighed to ascertain the gross weight of each package. 2. The Importers to give with each entry a statement that the Teas in each break have been bulked in India and that the chests of each break contain even net weights. 3. In order to test the accuracy of this statement, ten per cent of each break to be turned out and weighed net, but in no case are less than three chests to be turned out. 4. If the variation in weight of the test packages, from each other, be found to exceed two pounds, the whole parcel is to be tared. For instance, if the test package weigh net 79, 80, and 81 lbs. respectively, the variations would not exceed two pounds; but if one package be found to weigh 79 lbs., and any other 82 lbs., or more, than the whole break to be tared; unless the Importer and Surveyor consider that an average tare can equitably be given, in which case the tarers must not vary more than two pounds, as in the case of the net weights. 5. Duty is to be charged on the average weight of the packages weighed net, provided that when the average of the packages weighed net amounts to so many pounds and a half or more, the half or more will be charged as a full pound; when the fraction is less than a half it may be disregarded. 6. All Indian Teas bulked in this country are to be weighed gross and each chest tared. I am to add that the Importers are to be allowed the option of having Teas dealt with under the above regulations or under the general regulations on this subject laid down in General Orders 10 1881.—H. MURRAY, Secretary.

**

DR. BONAVIA has addressed the following interesting letter to the Conservator of Forests, Northern Division, Madras, on the subject of obtaining for experiment seeds of the fruit-bearing date-palm of Arabia (*Phoenix dactylifera*) to be sown in the Southern presidency, where planting of the common date (*Phoenix sylvestris*) and the Palmyra on the banks of rivers in the Cuddapah district has already been commenced:—

When I got offsets for the Lucknow gardens I got them through Government and the Resident of the Persian Gulf. If you write at once you may get them in November so that they may strike by the beginning of the hot weather. Getting them in the hot weather would entail greater loss. They should be got really in October. Then with ordinary care and watering more than 50 per cent will strike. In the hot weather they should be watered frequently and kept in the nursery, on the east side of trees for shade until the next rains. At the same time I got mine, 100 offsets were sent to Bangalore. They planted them out and neglected them. They all died. They thought, being a desert tree (it is never found in what is really called desert), it required no water! Of my offsets I saved 50 per cent and more; there are in Lucknow gardens 112 date palm trees from offsets and 232 raised from seeds, all from thirteen to sixteen years of age and fruiting. Some of them are 12 or more feet high. I am satisfied that the date palm is the famine tree for India. It thrives, lives and luxuriates

when rain is abundant and even tropical (drainage necessary at the roots), but it gives its best crop in times of famine. People think that, because its fruit when ripening rots in the monsoon, it is not suited to this climate. But this year even rice rotted in Bengal, and even jowar and indigo rotted. Ergo these are not suited to this climate! I feel confident that natives will not allow the dates to rot, as they are very good to eat in their unripe "kharak" stage, yellow or red. Persians live on *kharak* and fish. As it is getting a little late for offsets, you had better only ask for 100 this year and gain experience, and then next year go in for 1,000 and then 2 or 3,000 a year to reach you not later than 15th October. As to seeds, this is the season to write for them also through Government. The date crop is gathered now both in Persian Gulf and in Sindh and Moultan. The latter date is small, but excellent for famine purposes. You should get maunds of seed of the best varieties. Thacker, Spink and Co., of Calcutta, have a book of mine in the press—"Future of the Date Palm in India." It gives every information you may require about the cultivation of this tree and other information connected with it. If you write to them, they will send you a copy as soon as issued. I have no interest in its sale. I made a present of the manuscript to the publishers *pro bono publico*. If you get seeds now, you will gain a season; 99 per cent of the date seeds germinate. Care required during first years.

**

From the Resolution of the Board of Revenue on this subject, it appears that date plants were put out in Tanjore so far back as 1880 and 1881, and were obtained from Messrs. Gray, Mackenzie and Co., of Bussorah. These are said to have arrived in good condition, and that those obtained in 1880 were planted to the number of 184 at a place called Vedarniem, and did so well that in the following year 443 plants were obtained and planted out at Vetangudi. Of these, however, only 297 remained at the close of 1882, and all the remaining male trees were in a dying condition. This unfavourable result was attributed to the very unsuitable nature of the site selected. We are glad to note that the Madras Government have directed that measures should at once be taken to obtain 50 lbs. of seed of the best varieties of Arabian date from Messrs. Gray, Mackenzie and Co. of Bussorah. These are to be sown in suitable localities by the Forest Department. We hope to hear in due time the result of these measures.

**

The following is a summary of the German home trade taken from *Kuhlow's*, for the week ending 25th November 1885 :—

An event calling for mention in connection with the commercial history of the week is the opening of the Reichstag after its long recess of nearly six months. The inaugural speech referred to the new customs tariff and promised reforms in brandy and sugar taxation, which, indeed, have been desired for some time. Reference was likewise made to the North Baltic Sea canal scheme, to which we alluded in this place last week. Not less is it a matter for satisfaction to the commercial world for personal reasons than to the nation at large from the coast defence standpoint, that this project is now in a fair way to accomplishment. Commerce, especially so far as the Western parts of the country are concerned, is sure to receive stimulus when vessels are able to run through the neck of land which divides the mouth of the Elbe from Kiel Bay. Though there is no burning commercial question to engage the attention of the Reichstag this session—such, for instance, as the tariff question—there is a likelihood of trade and industry receiving a full share of discussion. Coming now to our review of the week, we are fortunately able to report a very decided improvement. The *Iron* trade has been cheered by the publication of further rail contracts of considerable amount and by the prospects of others in the immediate future. Business is as bad as before in Silesia, but in Rhenish-Westphalia a most welcome improvement has set in. The coal trade is well situated in accordance with the season of year, and in Upper Silesia the railway sale has been so great that there has been quite a dearth of waggons. The *Sugar* market is decidedly stronger. A good effect has been produced in the market by the announcement of a greater falling off in the production of Europe during the recent campaign than was expected. It need hardly be said that the soul of the sugar manufacturer and dealer has been cheered by the better outlook. The *Wool* trade has been somewhat better situated, the purchases of manufacturers having

been larger and more varied. It is believed that an upward tendency has set in. The demand for *Cotton* continues on the whole weak, though at some centres the market has been animated during the week, the present low prices having induced considerable operations. Spinners are not able to report better quotations. The second half of the month has brought life to the *Leather* market, in which there has of late been more business in almost all departments. Prices have been maintained in the *Corn* trade, but the trade in wheat, rye, and barley is poor, the disturbances in the East not being without influence. Oats are better. The *Wine* trade has been very dull, but great animation has characterised the spirit market, prices having risen all round. There has also been tolerable activity in the *Tobacco* market. On the whole the outlook is much better.

COTTON IN ASSAM.—I.

A short time back we noticed briefly the extent to which cotton was grown in Assam; we now propose to examine minutely the report submitted by Mr. H. Z. Darrah, the officiating Director of Agriculture, Assam, on this subject.

The variety of cotton which is chiefly found in Assam is the variety known botanically as the *Gossypium herbaceum*, which is also extensively cultivated in Southern Europe. As previously stated, the absence of accurate statistics renders it rather difficult to arrive at a correct estimate of the area under cotton. This is the more to be regretted, as in the Assam Valley, where alone the rudiments of a registering system are to be found, the crop is almost unknown; while in the hill districts, where no registering agency of any kind exists, cotton forms a very important article in the annual agricultural outturn; and the absence of any means of accurately gauging its amount is a matter of regret. In Lakhimpore, and Sibsaur, on the lower slopes of the Bhootan Hills, in Kamrup and Goalpara, cotton is grown to a limited extent; Nowgong is the only district where it is largely grown. This is due to the fact, as Mr. Darrah says, that the range of the Mikir Hills is included within its boundary. These people (Mikirs) grow cotton not only for domestic consumption, but also for export. The following figures are approximate estimates of the area under cotton in the Brahmaputra and Surma Valleys :—

			Acres.
Brahmaputra Valley	Goalpara	...	1,822
	Kamrup	...	248
	Nowgong	...	3,286
	Durrung	...	388
	Sibsaur	...	88
Surma Valley	Sylhet	...	100
	Sylhet	...	900
	Cachar (Sudder Sub-division)	...	500
Total			7,132

These figures relate to the plains districts; but in the range of mountains extending from the head of the Brahmaputra Valley to the confines of Mymensingh, cotton is nearly everywhere a staple crop, the one exception being the high plateau of the Khasi Hills, where, owing to the severity of the cold, it is altogether, or nearly, excluded. The Garos grow it very largely, and the inhabitants of the Khasi and Jaintia Hills, says Mr. Darrah, carry down hundreds of maunds every year to Kamrup and Nowgong. The method of estimating the outturn and the area under cultivation, is somewhat primitive, but the following figures furnish an approximate estimate of the actual area under cotton in the hill districts :—

			Acres.
Garos Hills	22,933
Khasi	1,250
Jaintia	3,500
North Cachar Hills	4,000

No estimate has been given for the Naga Hills, as no attempt, we are told, has so far been made to collect any statistics in this district. Adding the figures for the plains and hills, we have a total approximate area under cotton in the province of 38,815 acres.

On the subject of varieties, Mr. Darrah gives some interesting particulars. There are apparently only two well-marked varieties, the one being described as the large-seeded, high

growing kind, bearing white flowers. The pods are very large, sometimes as much as 8 inches in length, and when they burst, says Mr. Darrah, "the contents come out in a cataract of cotton, which gives a field the appearance of being covered with snow." But this variety does not seem to be in much request for ordinary purposes as the smaller kind, the fibre being said by the trade to be harsh and to twist badly; but it is said to be well adapted for mixing with wool. The other, the small-belled species, bearing reddish flowers, and particularly that grown in the Jaintia Hills, is said to be the best cotton grown in the province. Its recommendations being that the thread can be more closely woven than that of other kinds. Mr. Darrah also mentions a *khaki* variety found in Cachar and Manipore, the pods of which are described as not being of a uniform *khaki*, but containing a few white threads here and there.

(To be continued.)

BUNDS AND TREES ON PADUGAI LANDS.

[Communicated.]

The term *padugai* requires to be explained at the commencement. It is the Tamil name given to that portion of the land lying between the banks and the stream, or in other words the bed of the river from which the water has receded, and over which is deposited, in time of flood, the silt suspended in the water of a river. The area covered by it varies according to locality. In the Tanjore district, it is usually broad and extensive, but in other districts, such as South Arcot, it is narrow and limited. Generally it covers a space of 30 or 40 yards. The soil of such lands is generally more fertile than the adjacent plots, not similarly situated, and is fit more for garden cultivation. These lands can be brought to many uses. The plots near the river in the Tanjore district are thickly overgrown with reeds, and are generally covered over by trees of luxuriant growth. The portions of the *padugai*, situated near the bank, and not covered with reeds, are cultivated in some places with plantain; and in others they are under gardens. The banks are generally 5 or 6 feet high above the level of the *padugai* lands, which are as high again above the bed of the river. Thus the bank is 10 or 12 feet above the level of the river.

Now such cultivated plots and banks prevent the river from overflowing during the prevalence of floods, deserves to be examined. During the rainy season, when the river is full, if there be no high banks, the course of the current in places where the adjoining plots are low, is diverted, and the water thus finds its way into the interior. But by banks being covered thickly with reeds, this is prevented. What is termed "Vaganai" in Tamil is constructed for this purpose in places where the river threatens to take a different course. In such places it is found, a few years after the construction of such "Vaganai," that the level of the land has been gradually raised by the sand of the river being washed and accumulating upon its surface. The land then escapes all danger from the force of the current. It has been said that the planting of reeds and trees is always a sufficient check to the current, when the river is full during floods, but if the flood is excessive the plantation is no more able to check the current, and thus the water overflows the *padugai* lands. But the water cannot go farther. This is due to the presence of strong banks which obstruct the rush of the water into the adjacent villages and lands. The banks are usually strengthened by the plantation of reeds and grass. Ordinarily in rainy seasons we have water in the river to the depth of 7 or 8 feet; but when we have more, the bunds are a sufficient check to the water. It is only when the water is more than 12 feet in the river, that it can overflow the banks. This, as far as it has been observed, occurs very rarely. It is only then that the people stand in need of the assistance of the authorities to raise the level of the banks to a sufficient height. The people, therefore, in such places are safe and secure from floods and, consequently, from damages.

We have heard that many villages have been washed away and our damages were caused to the poor ryots during the floods

of late years. These calamities are due to the absence of preventive measures that ought to have been taken by the Government authorities, who do not, however, appear to take any precautions at such times. They feel the sense of their duty only when it is too late. They should be asked to plant reeds and trees on the dry beds of rivers, and to raise embankments; for, as shown above, these methods protect the people and their lands from floods. The Government ought to plant trees and strengthen the portions adjacent to a river, since they are all classed under Pannamboke, and as they belong to Government, private interference is punishable. This work, it may be remarked, will not prove unremunerative to Government, for there is some prospect of a revenue to be derived from it. The reeds and grasses would be readily bought by the poorer classes for thatching purposes, for fodder for their cattle, and various other purposes. It need not be pointed out here that trees will also give a proportionate income. Thus we find that these preventive measures, while affording security and protection to the people from floods, would form also a source of income to Government. It may further be stated that this would save the Government the heavy sums they are obliged to spend in times of floods. If the Government should find it inconvenient to take the measures advocated in this paper, it is suggested that the *padugai* lands of river side villages might be farmed out for cultivation purposes to the ryots under certain conditions, such as they should grow reeds in their respective plots and raise bunds in the same, while they may be allowed to cultivate the rest of their plots and reap the fruits of their labour without having to pay taxes. There is no doubt that they would be very willing and prepared to undertake the above, for it would enable them to have always a good supply of wood for fuel purposes, and provide for manure for their lands. It may not be out of place here to point out to the ryots as well as to the Government that the following trees, as they grow very quickly, yield capital wood for fuel and can be utilised for agricultural implements:—*Casurina Equestrifolia*, *Poinciana Regia*, *Cassia Florida*, *Calophyllum Inophyllum*, *Thespesia Populnea*, *Tuga Dulcis*, *Portium Canditum*, and *Odina Wodeer*.

SAHARUNPORE BOTANICAL GARDENS.

THE annual report on these gardens for the year ending 31st March 1883, is before us. Although the report bears evidence of good work having been done during the year, the financial results show a slight falling off. The total expenditure amounted to Rs. 33,230, or Rs. 160 in excess of that of the previous year; while the income amounted to Rs. 8,488, showing a decrease of Rs. 1,010 over that of the previous year. The falling off in the income is explained as being due to the temporary cessation of sales from the hill gardens, to a reduction in prices, and to an ordinary fluctuation in demand. Much seems to have been done to add to the appearance of the gardens, especially in the matter of carriage drives and footpaths. Our recollections of these necessary adjuncts in the Saharunpore gardens are not of the most favorable kind, but when we last visited these gardens, Mr. Duthie had only just assumed charge from Dr. Jamieson, the former superintendent, under whose direction, we fear, the gardens were allowed to run into a wilderness. If we remember rightly, the good doctor, though one of the ablest botanists in India, was very much averse to cutting away trees and jungle; and had no soul for the modern style of laying out gardens; we are therefore glad to see that the system of grass plots and shrubberies has been introduced into these gardens. Though a technically conducted botanical garden, we see no reason for omitting those artistic features which add so much to the beauty of the garden. A considerable falling off is observable in the distribution of plants during the past year; for while in 1883-84 there were 145,939, in 1884-85 there were only 42,216 plants sent out, showing a decrease of 103,723. The distribution of the *Agave americana* and strawberry suckers go to swell up the total for the previous year, as they in themselves number no less than 118,035. There is a sensible increase in the issue of acclimatised seeds, from 6,093 lbs. to 19,660 lbs. It is satisfactory to note that by far the greater bulk of these seeds were supplied to the general public.

The collection and preparation of drugs forms an important item in these gardens. The following are some of the drugs prepared during the past year :—

	lbs.
Extract hyosclamus	262
Dried leaves of „	289
Extract of taraxacum	31
Root of „	250
Kamalia powder	59
Colocynth fruit	119

Among the more interesting additions to the gardens, we note the species of *cousinia* sent by Dr. Aitchison of the Delimitation Commission. The *Napoleona imperiales* is a new species to India, and is a native of West Africa. It has a remarkably constructed flower, and yields a fruit resembling a pomgranate, from the astringent rind of which a kind of ink is made by the natives. The most valuable recent introduction, however, is the *Ipomoea purga*, which yields the jalap of commerce. Three hundred tubers were, it seems, obtained from the Nilgiris, and planted at the Arniguth garden at Mussoorie, where it is said to be doing remarkably well. The vegetable sowings were more or less failures, having been damaged by the heavy rain of October.

The experiment with potatoes is interesting. It appears that the varieties that have been acclimatized already, and are known as the ordinary country kinds, have given the best results, both in point of yield and quality, and Mr. Duthie pronounces them superior to the imported varieties. The results of three years' successive trials certainly prove the fact that the country kinds, under proper treatment, yield the best crops; 135 maunds to the acre is, we think, very satisfactory evidence of this fact. The trial of the Italian field turnip shows that the leaves outweighed the roots by a great deal, and Mr. Duthie remarks that "if it is intended to use the foliage of the plant and not the root, as one would have supposed, the experiment is so far a success." The Indian corn experiments showed that, of the imported kinds "Stowell's evergreen sugar corn" was the best of the American varieties. The Kumrah of New Zealand (*Ipomoea chrysocoma*), a species of sweet potato, is considered to be a valuable addition to our varieties of vegetables.

On the subject of cereals, there are some interesting remarks on wheat and barley. Mr. Duthie states that amongst some contributions for the Kew Economic Museum, he took home two samples of grain, one of a variety of wheat called "Gujaria," and grown at Saharanpore from selected seed (the original having come from the Cawnpore Farm years ago) and the other a remarkable variety of loose grained barley of a dark chocolate color, grown from a small sample exhibited at an agricultural show at Saharanpore by a zemindar of the Mozaffernugger district. These samples were considered by Professor Thistleton Pyer, the Assistant Director, Kew Gardens, to be of sufficient interest for being specially reported upon, and he accordingly sent them to Mr. McDougall, the well-known expert in matters relating to cereals, who reported as follows :—

We had much pleasure in receiving your letter of 11th instant, with samples of wheat and barley. I have shown them to most of the principal people in the corn market, who took much interest in them. The wheat is valued at about 30s. per 496 lbs., it being classed with the Kubanka (Russian wheat) its bright and clean appearance causing much remark. On grinding and pasting, I find it contains much gluten, but is somewhat sticky. Is there any particular reason to grow this seed, as I think it would pay better to grow the white seed such as is now shipped from Bombay, and is now worth say 39s. per 496 lbs. here. Quantities from this (your) sample would at once command a ready sale, and if you could procure say 20 quarters, I shall be glad to grind and bake it and report to you. The barley: This was looked at with much interest, and many opinions expressed upon its being quite new; the value varied from 23s. to 30s. per 400 lbs, I notice on dampening it that each grain sprouts well and so will malt, but the color comes off and so would not do (it is thought) for pale ale, but it might do well for stout. For feeding purposes it would be useful although it would take time to remove prejudice to its color. Is this seed likely to grow better than the ordinary barley or is it possible to grow a huskless barley of the ordinary color? I am much obliged to you for sending these samples, which

are so very interesting, and shall always be pleased to give you any information in my power.

The following remarks by Mr. Duthie on this subject are worth reproducing :—

The wheat is a very hardy free-growing sort, and always gives a good yield both in grain and chaff. Last season the yield was 18 maunds and 13 seers chaff per acre. This variety possesses the good quality of being able to stand well up when grown in highly manured soil; for, as is well known, most varieties of Indian wheats run up into straw and fall over before coming to maturity when the soils are too highly manured. This variety is thus well adapted for those who attempt to cultivate wheat according to the European method.

The chocolate colored barley produced 15 maunds grain and 12½ maunds straw per acre. The yield of grain was thus heavier than the yield of straw. The objection as to color alluded to in the report is fatal to its value, and will prevent its ever being grown except as a curiosity. We possess a white-grained variety of huskless barley, and a good large sample of this has lately been sent to Kew for special report. The huskless barleys appear to be quite unknown in England, and as everything except color was favourably commented on in the case of the variety sent, I am in hopes that the report on the white variety will be altogether favourable and perhaps become the means of bringing this barley to the notice of the English markets. The three varieties of oats, viz., "Challenge," "Irish White," and "White Russian" have again done well. Only a small proportion of the seed sown germinated; this is always, however, the case with seeds saved from freshly-imported cereals. The whole of this season's heads are well filled up with grain, and in another year I shall probably be able to give some idea of the yield per acre.

(To be continued.)

AN ENTOMOLOGICAL LECTURE.

On the 18th instant there was a large gathering of ladies and gentlemen at the Dalhousie Institute, having been invited by the Honorary Secretary to see a splendid collection of insects made by Mr. Mowis in Sikkim. The cases containing the collection had been laid out in the Institute, and almost formed an exhibition of themselves, though they are intended for the Indo Colonial Exhibition in London. Every class of insect was represented, and the gorgeous colours of some of the butterflies and beetles baffled description. Shortly after 9 o'clock, the Honorary Secretary introduced Mr. Mowis to the audience, and the lecture which followed was listened to with the utmost attention. Free from all technicalities and abounding in amusing stories out of the history of insect life, Mr. Mowis's comparisons of the different powers and faculties of insects to be met with in insects, made up a concise and able disquisition that kept his audience thoroughly interested. In addition to interest as a lecture, there were facts made known of real importance and great practical value. We quote the part relating to silk and sericulture of India, and only wish we could give it in *extenso*. Describing the three great silk-producing families of moths, the lecturer said that the first family contained all those cultivated and domesticated by men; secondly, those that are left to themselves to weave their silk in the jungle, and are called wild silk-worms; and thirdly, those silk-worms which spin a cocoon, but have no commercial value at present. In former years, he said, India had a very large silk industry, but owing to prevailing diseases of the silk worms and years of drought, it is now scarcely one hundredth part of what it once was. Government had made many efforts to revive it, and tried hard and incurred heavy expenses to give a new impulse to this industry, but though land and labour are cheaper here than in any other part of the world, the lecturer was doubtful whether the mulberry silk would ever regain its former footing in India. It takes, we learnt, three years to make a plantation fit to feed the worms to make good marketable silk, so that it is impossible to attempt any large scheme; but as the lecturer remarked, if we are unable to obtain the best silk except at a loss, get the next best that pays—and pays well. Therefore every encouragement should be given to the tussar industry in this country. Mr. Thomas Wardle has just reached this country, having been sent out by the Home Government to investigate our silk industries. He was the British delegate at the late Paris Exhibition, and has demonstrated the fact that tussar silk can now be reeled and spun, bleached and dyed, in splendid colours, and is used in almost any material where formerly the best silk only were employed. A demand has, therefore, sprung up where there is at present but a limited supply. The tussar cocoons are found

In every part of India, and the worms feed on almost every plant. They are very hardy, and little liable to disease, and if Government would only take the matter earnestly in hand, we should have a most extensive industry in the space of a very few years. This new industry would almost equal the waning cotton one, and prove much more remunerative, while giving employment to thousands of the poorer classes to whom this work would be particularly well suited, thus adding largely to our revenues. Lakhs of rupees' worth of these cocoons are shipped home every year, taking up great space on board ship. These cocoons have to be reeled at home on spindles which cost £75 each, and by labourers who demand 20s. a week. The same result could be obtained here with labour at 5 rupees per month. The great drawback in all native-reeled silk has always been the unevenness and lumpiness of the thread, but with very little trouble, an improved reel could be introduced here, which would give all the desired evenness. The lecturer exhibited a model reel, which has been constructed by him, and which combined to a certain extent both the European and native methods, and still remained simple enough to suit unskilled labour. The cost of this reel is so low as to be within the reach of the poorest coolie of the country, and by a general adoption of such a reel or a similar one, Indian-reeled tussor silks could be laid down in the European markets at about 10s. per pound, and thus give 100% profit on the outlay! In explaining this reel, it was shown that it reeled evenly, and distributed the silk regularly on the reel, from which it can be removed by a very simple contrivance, without disturbing the layers of the silk, which is very essential. It could be worked by hand or foot, and also be adapted to machinery, and any child could learn to work it in a short time. A case of sample silk was exhibited, which had been reeled on this model, and a small quantity was also reeled before the audience in the lecture hall.

At the conclusion of the lecture, Mr. Simmons rose to propose a hearty vote of thanks to Mr. Mowis, for the very instructive and able lecture they had all listened to, and for having so kindly lent his collection on view, remarking at the same time that lectures of this class were much more likely to be appreciated, than many others which are either too technical or too classical for the general public. Bombay had, he said, a Natural History Society which was doing much good. Calcutta has several scientific societies, but as they are mostly confined to old monuments and coins, it interested only a limited number, whereas a Natural History Society would be liked by many, for even children could be taught many good examples from the very book of nature. The lecture they had just listened to was one particularly suited to stimulate them, and the chairman thought a combined effort should be made to form a Society of Natural History here in Calcutta. The company then separated.

Miscellaneous Items.

MR. W. D. GUNN, Veterinary Surgeon, Central Provinces, has been rewarded by Government with Rs. 5,400 for his report on Cattle Disease.

RAO BAHADUR LALSHANKAR UMISHANKAR, Sub-Judge of Ahmedabad, has been granted Rs. 3,000 for compiling certain arithmetical works for the use of students.

THERE has been heavy rain in Lahore during the last few days. Rain was much wanted, not only in Lahore, but in almost every part of the Punjab.

THE rice crop in Orhoo, and indeed all along the Nepal frontier, has been unusually good and abundant this year. A brisk export trade is already beginning, and prices are low.

A TELEGRAM from Madras to the *Times of India* says that increasing attention is being given there to the Mysore gold mines. Eleven hundred ounces of gold from the Mysore Company's mines were shipped home by the last steamer. A great advance in the value of the shares of this company is advised from London. Other mines are looking up.

THE quantity of tea exported from China and Japan to Great Britain, from the commencement of the season to the 24th of November last, was 131,638,088 lbs., as compared with 129,984,683 lbs., during the corresponding period of last year. The exports to the United States and Canada during the same period have been 63,171,205 lbs., as compared with 59,760,491 lbs.

SOME correspondence has recently taken place between the Government of the North-West Provinces and the Supreme Government on the subject of the alleged decrease of the area held under occupancy right in the former province. A careful enquiry was set on foot by the Board of Revenue, selected villages being subjected to a minute scrutiny, and the whole question being thoroughly sifted in the light of the now fairly trustworthy statistics obtained from the putwari's records. The result goes to show that the alleged decrease exists rather in name than in fact. Whilst the area recorded as held by tenants with rights of occupancy at the late revision of settlement, has undoubtedly decreased, the loss has been more than compensated by a steady growth and extension of occupancy rights on other lands. We find in fact that, whereas out of the area of 7,713,866 acres held by occupancy tenants at settlement, 1,070,778 acres or 13.9 per cent has been lost; in 1,814,109 acres or 20.9 per cent of the area at settlement, occupancy rights have since accrued.

DURING the last few days the citizens of Bombay have had a chance of forming an idea of what the Bombay Court will be like at the Colonial and Indian Exhibition. A large portion of the elaborately carved screen, which will go round the Court, was exhibited by Mr. Wimbridge. Mr. Van Ruith gave a private view of his pictures. Mr. Griffiths showed at the School of Art as many of the fabrics as could be conveniently unpacked. Mr. Terry opened the doors of the Wonderland Pottery Works, and the models of Indian craft were exhibited at the Dockyard. Every one was pleased with the general result. Bombay, there is no doubt, will be very worthily represented. We understand, however, that the Bombay exhibits will not be accompanied by a custodian. But surely this is a fatal blunder likely in itself to defeat the primary object that prompted the collection of so excellent and so representative a series of articles. Exhibits have been sent mainly in the idea that the adequate representation of Bombay artwork in London would develop the trade of this presidency, and lead to larger dealings with England. Mr. Griffiths, the secretary of the local committee, is the gentleman we should like to see sent home in charge of the Bombay exhibits. But if this be impossible, a very good substitute could be found in Mr. B. A. Gupte, his head clerk. Mr. Gupte has an intimate and technical knowledge of all the Bombay art industries. He is a well known authority on the subject. In five minutes conversation he could probably tell any English dealer more about any fabric or any ware than could be gathered from hours of study. What is more, he is intimately acquainted with the producers on this side, and could put the English consumers into direct connection with them. He would also have the opportunity of learning while in England what qualities of goods are best suited to the English market. After all the money that has been spent in the Bombay collection it would be a pity to risk the loss of the ship for the want of a halfpenny worth of tar. Mr. Gupte's expenses could not be heavy while the possibilities of a good return would be very promising.

Selections.

ENSILAGE AT ALLAHABAD.

As the experiments in ensilage conducted during 1884-85 at Allahabad in connection with the preservation of grass, were perhaps larger and more comprehensive than any experiments which ever took place at any other one place, I propose submitting a report, showing generally the process of this method of the underground preservation of grass, and in detail the contents and outcome of the several silos dug in Allahabad cantonments.

Eighty-four silos in all were dug, and filled with grass, &c., between 23rd July and 29th October, 1884. The dimensions of the majority of these were 30' x 12' x 6', while the rest were of various sizes.

The silos were so situated, as to be in the centre of the plot, from which it was intended the grass should be cut. This was done to avoid the necessity of engaging carriage to take the grass to the pits, and by these means the only expense incurred in filling the silos was the contract rate of cutting the grass, viz., about 9 pie per mound.

It was found by experiment that a field or plot of about five acres of ordinary grass land, will fill a silo 30' x 12' x 6' dug in the centre of it. The coolies who cut the grass will carry it and throw it into the pit.

The cost of three silos of the above size was Rs. 11, or at the rate of Rs. 1-11-2 per 1,000 cubic feet. In addition to Rs. 3-10-8 for excavating the silo, there is the charge for covering and uncovering it with $\frac{1}{4}$ feet of earth which is about Rs. 1-5-4, and hence the total expense connected with a silo 30' x 12' x 6', containing 600 maunds of grass, should be about Rs. 5.

The principle on which these experiments were carried out, was to find out the very cheapest method of preserving grass, karbi, mothi, &c., so as to bring it within the power of the poorest villager to store food for his cattle. It was with this object that only earth silos were dug, no elaborate means of draining or pressing were attempted, the experiments were conducted in the simplest and cheapest form, and though a small percentage of the silos was not good, yet on the whole the experiment may be deemed to have been highly successful, and considering that the operations were nothing more than digging a hole in the ground and filling it with grass, it is highly satisfactory that over 40,000 maunds of food so stored should have been eaten, and eaten with relish by the cattle (numbering 1,000) and upwards of 1,200 ponies.

To examine the financial results of the above operations it will be seen that, roughly speaking, the silos containing these 40,000 maunds of fodder cost Rs. 350, and the cost of cutting the grass was Rs. 1,875, and thus giving even the liberal allowance of 40 lbs. per head per bullock per day, it would be possible to feed 80,000 cattle for Rs. 2,225, or in other words, to forage over 200 bullocks daily for a whole year at a total cost of Rs. 2,225, or at the rate of Rs. 11 per bullock per annum.

Now at the most moderate computation and giving only 20 lbs. per diem, it would cost to feed a bullock on bhusa Rs. 45 per annum, or more than four times as much as the ensilage. This is taking the rate of bhusa at 8 annas per maund.

The only precautions necessary in filling an earth silo, are to heap the grass as high above the surface of the silo, as the depth of the silo, and then to cover the grass so heaped up with the whole of the earth which has been previously excavated, care being taken to cover a margin of 2 feet all around the sides of the pit to keep out air and water. With a few exceptions nearly all the Allahabad silos were filled while it was raining hard.

When a silo has been covered up, great care must be taken in filling up any cracks or crevices the moment they happen to appear.

For the first twenty-five silos that were made, an elephant was employed to press the grass, but subsequently the services of the elephant were dispensed with, and no pressure other than the weight of the excavated earth was used. The latter appears to be quite sufficient, and is the least expensive form of pressure that can be applied. It is of course highly important that the weight of the earth so put on should be equally distributed.

Another form of pressure that was tried was wooden sleepers; but unless great care is taken in placing the grass evenly, it is very difficult to obtain an equal pressure, as the sleepers being flat will naturally press only on the highest points of the grass. Our experience seems to show, that the earth pressure is all that is necessary, if carefully applied.

A most important result was obtained from 12 silos, which were made along the line of rail between Allahabad and Manauri, for though they were filled almost entirely with the coarsest description of grass, viz., kusa, kana, and ganhra grasses, which make poor hay, yet the ensilage turned out excellent.

The coarse grasses came out of the silo soft and succulent, and that they were nutritious and palatable was proved by the condition of the bullocks during the issue of this ensilage, and by the greedy manner in which the animals devoured this fodder.

I think also that results proved that for the purpose of being siloed, grass should be cut either with the "jabao" (small circular scythe) or with the "bassa" (sickle), and not with the "kurpa," for with the latter it is almost impossible to avoid scraping up dirt and roots, which not only make the ensilage gritty and unpalatable, but also tend to cause it to have an obnoxious smell.

After opening the silos on the railway, we opened eleven that had been dug on the Fort Esplanade. These were formed from the following good grasses, viz., bandari, junevahi, muscel and dhob, and turned out excellent. These grasses had been in the pits about six months, and came out as green as when put in.

I then had to open out the silos in new cantonments. These did not turn out so well as those on the railway and fort, and three or four were so bad that they had to be closed again. The smell of this ensilage while in the pit was nasty, but when removed and exposed to the air, it became unpleasant, resembling

a tan-yard in smell. Most of it, however, was greedily devoured by the cattle, though some three or four silos could not be used.

The reason the silos in new cantonments were not so good as the others can fairly be attributed to the fact that the grass put into them was immature and young, and from this the following deduction can be made:—Ensilage to be good should be made from grass cut just before it flowers, and this will allow a good second crop to spring up for hay.

The Transport Lines in Allahabad are in every way inconveniently situated, being in what are called the Chatham Lines, three or four miles away from the barracks, commissariat godowns, and other places in which the bullocks are called upon to work. This necessitates most of the bullocks for duty having to walk four miles before their work is begun, and again to perform a return journey of four miles when their work is finished. Carrying the ensilage to the Chatham Lines was fraught with a great deal of inconvenience, for to get there from new cantonments necessitates passing through the greater part of the civil station, the inhabitants of which naturally complained of the smell of the ensilage. As soon as it was found that annoyance was being caused, the issue of ensilage to the animals in the Chatham Lines was stopped.

Ensilage has a curious smell, very like that of a tan-yard, which is unpleasant to any one unaccustomed to it, but which ceases to be unpleasant after one is used to it. There is nothing to show that the smell is at all unhealthy, on the contrary the coolies who were employed daily on the silos, kept in excellent health, and the siege train bullocks who were fed almost entirely on it, kept well and in very good condition. There was only one death amongst these animals, and that was caused by rinderpest. This epizootic disease spread considerably amongst the new bullocks bought for the proposed expedition for Quetta, and caused many deaths. The commissariat slaughter cattle were fed almost entirely on ensilage, and nothing else, with the most favourable results. I mention this as an idea seemed to have gained ground, that the deaths amongst the new purchases were due in some way to the ensilage. This can hardly be maintained in the face of the following facts:—

(a). Siege train bullocks fed on ensilage from the time of the first silo being opened, to the last being closed, kept well and in good condition.

(b). Slaughter cattle same result.

(c). Slaughter sheep fed partially on ensilage with good results.

(d). Ponies fed on ensilage.

I think it has since been incontrovertibly proved, that the deaths among the new bullocks were due to rinderpest, and that the disease was raging in the villages round about Allahabad is well known, and was witnessed by the Major-General and Deputy Assistant Quartermaster-General of the Division, who, when out in the district, saw the corpses of many hundreds of bullocks that had been carried off by this disease.

I made an experimental silo with wonderfully good results. It was filled in the following manner:—At the bottom was placed about 2 feet of green "mothi," next some rather dry munj; on this came some 2 feet of chaffed sorghum, then a layer of dry karbi, pressed down by about 6 inches of green mothi, and on the top of all a layer of sorghum. This pit was opened on 13th May, 1885, after having been covered for 6½ months. Two inches sorghum at the top had to be discarded. The remaining articles came out most excellent, the dry karbi appearing as juicy and fresh as the green. The animals devoured this ensilage in the greediest manner.

I attach a statement* showing the result of each silo in detail and in conclusion I submit the following summary of what would appear to be the facts ascertained in connection with this most interesting experiment, which was conducted on so large a scale at Allahabad this year:—

(1). It does not appear necessary to go to the expense of building masonry silos, or to take any particular precautions in draining and pressing, as an earth silo seems to fulfil all the necessary conditions, and apparently drains itself if kept air and water tight.

(2). The only pressure that seems to be necessary, is that caused by the excavated earth being piled on the grass.

(3). The best time to cut the grass is when it is mature, between 15th August and 1st November; this will give a second crop for hay.

(4). The fact of its raining while a silo is being filled, does not appear to do any harm.

* We are obliged to omit this for want of space.—Ed., J. A.

(5). The ensilage should be issued green, i.e., as it is taken out of the pit.

(6). Thirty-five lbs of ensilage would appear to be equal to 20 lbs. of bhuna, the ration of a siege train bullock.

(7). Ensiled karbi forms good food for elephants.

(8). The fact of cutting the grass for ensilage, gives a finer and better second crop for hay-making.

(9). Silos should, in my opinion, be made wedge shaped, i.e., rather wider at the top than the bottom, and with sloping sides, to preserve an even pressure. The floor and sides might be baked by burning rubbish in the pit.

I trust that the experiments at Allahabad may in the course of time show the villagers and country people, that they have now a sure and safe means at hand for preserving food for their cattle, and a cheaper method by far of procuring good fodder than any now in existence; and in conclusion I would point out that the success of these experiments is mainly due to the intelligence and hard work of Sergeant Meagher, of the Commissariat Department, who has not only been out in all weathers, but has taken an intelligent interest in the operations, which has gone far to make them so successful.

S. C. F. PEILE, Captain,
Assistant Commissary General.

EXPERIMENTAL BOTANICAL GARDENS.

From M. A. LAWSON, Esq., Director of Government Gardens and Parks, &c., Nilgiris.—To the SECRETARY to Government, Revenue Department,—(No. 313, dated Ootacamund, 13th November 1885):—

I have the honor to acknowledge the receipt of Proceedings of the Board of Revenue, dated 1st October 1885, No. 2783, together with (G.O. S., dated 26th October 1885, No. 1168, calling for any remarks which I may have to make upon their proposal to establish experimental botanical gardens recommended by them at Gudalur, Kuttalam, Russellkonda, Hovur, Ramandrug, Yercaud, Chittoor and Palmaner.

2. I will at the outset observe that the object of establishing experimental gardens is to discover in what particular districts plants of commercial and other value may best be cultivated, and therefore that the localities selected should differ from one another, as much as possible, in temperature, rainfall and character of soil, so that it would be a waste of money and energy to establish more than one garden where the above conditions are similar.

3. Mr. Galton, acting Collector of Bellary, writes that there is "a garden situated in a basin just below the plateau of Ramandrug, which was formerly a soldier's garden, and is the property of Government." This, so far as I can tell without actual examination of the site, would seem to be a most eligible site for a garden. It is in the plains, and the proposed site is already the property of Government.

4. The remarks made by Mr. Burrows, Collector of the Nilgiris, respecting Gudalur, I can corroborate from personal knowledge. It is about 2,500 feet above the sea, has a heavy rainfall, and would represent very fairly what might be grown upon the Wynad plateau generally. Mr. McWatters, Collector and District Magistrate of Salem, strongly recommends a garden in the neighbourhood of Yercaud on the Shevaroy Hills, and he encloses a most practical and interesting letter on the subject from Mr. Shortt. I do not think, however, that the differences between the climate and the soil of the Shevaroy Hills and those of the Nilgiris Hills are sufficient to warrant my proposing to Government that a garden should be established here. I say this with a special regret, for no one who knows Dr. Shortt's botanical work would be willing to lose the experience and advice which it is certain he would have been ready to give in all cases of doubt and difficulty.

5. Mr. Lee-Warner, Collector of Tinnevely, makes several very valuable suggestions. He points out how Government have been great pecuniary losers in past days by establishing spice gardens where their management had been neglected, and he most truly states that we should take the lesson which history teaches, and not attempt to establish any new garden unless a permanent expert cultivator can be guaranteed. I entirely agree with Mr. Lee-Warner, and it would be the business of the Central Botanical Department to train gardeners, who should be fitted to hold the head overseerships of all gardens which Government may decide upon establishing.

6. Mr. Lee-Warner further gives it as his opinion that there are many planters who would be quite ready to assist any experiment which Government might wish to make. My obligations

to gentlemen of this description are too many to allow me to doubt for a moment Mr. Lee-Warner's statement; but the planter has generally too much upon his hands to pay that close attention to the cultivation of new plants which is so necessary, when the conditions of their growth, in a new country, are imperfectly understood. Mr. Lee-Warner speaks highly of the country about the falls of Kuttalam, and as this is a place of great botanical renown, I do not think that Government could do wrong in establishing a garden here.

7. In addition to the above, I think that a garden in the neighbourhood of Russellkonda in Ganjam would prove of use, as it is in the extreme north of the presidency and on the east coast. I do not however know anything of that part of the country.

8. I would suggest then that, in addition to the gardens at Ootacamund, Coonoor, Barliyar, and the one sanctioned at Calicut, there should be established four new ones, Ramandrug, Gudalur, Kuttalam and Russellkonda. If these new gardens are sanctioned by Government, the cost of making them and the cost of their upkeep would be as much as Government would find advisable, while their proper inspection would occupy as much time as the head of the Botanical Department could conveniently afford.

AGRICULTURAL EDUCATION.

PROFESSOR WALLACE, in his inaugural address in the Edinburgh University the other day, dealt with some important points connected with the above subject. His remarks on the importance of landed proprietors and their agents being thoroughly instructed in the principles and practice of farming were as well timed as they are sound. Proprietors, it is felt on all hands, have hitherto left far too much to their factors in the management of their estates. Even where the latter are thoroughly qualified for the work, the relationship of landlord and tenant would be on a far more cordial and satisfactory footing were the former to look more closely into their own affairs. When the parties are brought together more or less frequently in the transaction of business that concerns them both, they are led to understand each other better, there is less friction, and, in fact, a more cordial relationship springs up between them. To enable them to fulfil their part with intelligence, judgment, and justice to their own interests, it is indispensable that they should be well acquainted, both theoretically and practically, with farming matters. Agents, however, must be employed to some extent to transact necessary business in the absence of their principals, and to carry out what has been determined on. There is the same reason, therefore, why they should have undergone a thorough training not only in the details of estate management, but also in practical agriculture. It has often been said, with too much truth, that lawyer-factors have been the curse of Scotland. Too often they have done not a little to embitter the relationship between landlord and tenant. They seldom know much about land, and some of them have the additional weakness of not being conscious of their own ignorance in the matter. The sooner they are superseded entirely by intelligent practical men who know their business, the better for all parties concerned. An able factor, who has had the great advantage of both a scientific and practical training, can often do much by counsel and encouragement to develop the natural resources of an estate, and thereby confer a substantial benefit upon both the parties between whom he is called upon to act.

This severe depression has done more than anything else to dispel the very prevalent idea that any person on a day's notice was qualified to be a farmer. The popular idea might be expressed by a parody of a well-known couplet of Byron in his *English Bards and Scotch Reviewers*—

'Man serves a time to every trade save
Farming; farmers all are ready made.'

Professor Wallace thinks that the best scheme by which to give the rising generation a thorough acquaintance with both the scientific and the practical sides of farming is to get them to study in the class-room during the winter months, and undergo a course of practical instruction on the farm during the summer. It would, no doubt, be better to have an agricultural college with a full staff of professors, and a mixed farm attached to it, where the practical could be taught alongside of the scientific and theoretical. That, however, is not very easily obtained. If agricultural students take part in the work of the farm for, say, three or four hours daily, except for brief periods at the busiest seasons, when the working time might be extended, they will have ample opportunity of becoming acquainted with practical work, and at the same time

• they will have sufficient time and buoyancy left to pursue their studies in the class-rooms. In fact, they will do this all the better because of their invigorating exercise out of doors. Residence on a farm for a season or more might follow, although it cannot be denied that in many cases the benefit which 'mud pupils,' as they are popularly called, derive from such residence on a farm is not commensurate with the time and money expended thereon. Many may not sympathise with Professor Wallace's objections to that feature of the elementary school system in Scotland and England which prevents children of tender years being kept away from school to assist on the work of the farm. The system of cramming, too commonly practised in Board schools, is highly objectionable, but irregularity of attendance is incompatible with steady and satisfactory progress. Besides, after all, what can a young child—say, under 12 years of age—do to assist in overtaking the work of the farm? It would do children destined subsequently for farm work far more good if teachers were encouraged to impart to their senior pupils in rural districts a knowledge of the elements of agricultural science, in such a way as to help them to understand the reasons, for much of the work they will afterwards be called upon to perform. Elementary technical instruction might be given in the public schools to the sons of farmers and agricultural labourers. The latter would thereby be made better workmen, and being of more value to their employers, they would be deserving of increased remuneration.—*North British Agriculturist.*

AGRICULTURAL EXPERIMENTS IN ENGLAND.

THE following is the report of Dr. A. J. Voelcker on the experiments at Woburn, Bedfordshire, submitted to and approved by the last meeting of the Council of the Royal Agricultural Society of England :—

WOBURN EXPERIMENTS, 1885.

A.—STACKYARD FIELD.

1.—Continuous Growth of Wheat.

* The wheat was cut and harvested on 20th and 21st August all being got in exceedingly well. Thrashing and weighing commenced on 20th October.

Speaking generally, the produce was lower than in 1884, and more like that of 1883.

The unmanured plots, the ninth successive crop, gave 21·3 and 21·9 bushels per acre, as against 23·1 and 26·6 bushels last year. Mineral manures alone only increased the produce to 22·4 bushels. 200 lb. ammonia salts per acre, on the other hand, gave a yield of 31·2 bushels, and 275 lb. nitrate of soda of 28·1 bushels, the increase in either case being comparatively less than last year, ammonia salts, as then, giving the higher yield. Minerals, with 200 lb. ammonia salts per acre, produced 37·5 bushels; and minerals with 275 lb. nitrate of soda per acre 38·9 bushels, the nitrate having a slight advantage. With double the quantities of ammonia salts and nitrate of soda in conjunction with minerals 41·1 and 40 bushels were obtained respectively, the yields in 1884, when no nitrogenous manures were applied, being 32·5 and 21·9 bushels. On the other hand the plots which last year gave 48·8 and 51 bushels when manured with minerals and 400 lb. ammonia salts per acre in the first case, and minerals and 550 lb. nitrate of soda in the second, now, on the omission of the nitrogenous manures for this single year, yielded only 24·7 and 18 bushels.

It will be noticed that the difference of produce of corn as between ammonia salts and nitrate of soda has this year been practically nothing; but there has been a considerably larger yield of straw with the nitrate, 200 lb. ammonia salts per acre giving 31·2 bushels of corn and 25 cwt. 2 qrs. 10 lb of straw, while 275 lb nitrate of soda per acre gave 28·1 bushels of corn only, but as much as 28 cwt. 0 qrs. 21 lb, of straw. The double quantities, in conjunction with minerals, gave, in the case of ammonia salts, 41·1 bushels of corn, with 45 cwt. 2 qrs. 14 lb. straw; in the case of nitrate of soda, 40 bushels of corn and 53 cwt. 0 qrs. 20 lb. straw. The weight per bushel of the corn was much the same in either case. Where farmyard manure was applied at the rate of 4 tons per acre for the ninth successive year the yield was 22·1 bushels, or 1 bushel only above the unmanured plots; applied at the rate of 8 tons per acre it gave 31·8 bushels, against 35 bushels in 1884. Where farmyard manure had been given each year up to 1882, and omitted since then, only 18·3 and 20·1 bushels were produced or rather less than on the unmanured plots.

2.—Continuous Growth of Barley.

The barley was cut 25th August, and carted the next day. It was thrashed and weighed 20th October and following days, all being in good condition. With one exception the yield was lighter than in 1883. The unmanured plots gave for the ninth successive crop 21·8 bushels and 22·5 bushels, as against 32·3 and 38·3 bushels in 1884. Mineral manures gave no increase, 21 bushels being the produce. 200 lb. ammonia salts per acre increased it to 34·6 bushels, and 275 lb. nitrate of soda to 37·2 bushels; minerals added gave a further increase in each case to 48 and 50·3, while the same minerals with a double quantity (400 lb.) of ammonia salt gave 58·7 bushels, and with a double quantity (500 lb.) of nitrate of soda 64·5 bushels, the latter being the highest produce of any of the plots. It will be observed that in the case of barley, nitrate of soda did better than ammonia salts. When nitrogenous manures, through applied with minerals in 1884, were now omitted, the yields were 39·3 and 34·8 bushels only. With farmyard manure the crops were lighter than in 1884.

3 — Rotation Wheat.

The respective yields were :—

	Bushels.
Decorticated cotton-cake dung	49·4
Maize-meal dung	53·1
Equivalent in artificials to decorticated cotton cake dung	44·8
" " maize-meal dung	47·6

4 — *Rotation Barley.*

The yield of the four plots were :—

Decorticated cotton-cake dung	62.4
Maize-meal dung	58.6
Equivalent in artificials to decorticated cotton-cake dung	63.7
" " " maize meal dung	59.9

5.—*Relation Taren.*

Tares were grown in plots, 1, 2, 3, 4 of rotation 1 without manure, but the prolonged drought almost entirely spoiled them, and they were thoroughly lighted. They were, however, cut early in August, but while on the ground, a gale springing up, blew the produce of the separate plots to all parts of the field, so that it was impossible to separate them. They were not worth thrashing.

6.—*Rotation Peas.*

These also suffered sadly from the drought and blight. They were cut early in August, and thrashed October 20, the yield being a miserable one. No manure had been applied to any of these plots this year.

Decorticated cotton-cake plot	15
Maize meal plot	12
Equivalent in artificials to decorticated cotton-cake	11
" " " " maize meal	13

7.—Rotation Swedes

These, considering the want of rain, have done very fairly well, and will be ready the middle of November.

8.—Rotation Mangolds.

A fair even crop, and are now being pulled.

B.—LANSOME FIELD.

The barley was out and stacked August 26-28, and will be threshed shortly. There is a good crop of clover on all the plots.

C.—WARREN FIELD.

This barley has also been cut and stacked, and will be thrashed soon. The clover, though not as good as in Labrousse Field, is a very fair plant.

D.—CLOVER AND GRASS EXPERIMENTS

It is proposed to plough up and re-sow with pure seeds all the grass plots in Stockyard and Warren fields. Also, the red clovers and alsike having entirely died out on almost all the plots, these plots will be dug up and re-sown. The white clover plots, which still are fairly luxuriant, will be left as they are. Three acres of land have been selected in another field—Great Hill Bottom—and will be sown in spring with grass seed mixtures of varying sort; the separate grasses will also be sown on small plots in the field.

E.—ENSILAGE EXPERIMENTS

Silos 1 and 4 have been re-siled—No. 1 with 3 tons 12 cwt. of meadow grass to be converted into 'sweet' silage; No. 4, with 15 tons 3 cwt. of meadow grass, to be made into 'sour' silage. There is also available for feeding experiments Silo 3, containing silage made from 18 tons 3 cwt. of green oats (shaded). Tubs to correspond to the above have also been siled.—N. B. Agriculturist.

THE ORCHARD OF AMERICA.

ONE of the surprises prepared for the visitors to the St. Louis fair was a display of the choicest fruits ever grouped in a single exhibit to feast the eye and tempt the appetite. It outranked and outvalued all competitors, and was crowned with a wealth of blue ribbon awards, most honestly bestowed. This fruit, which we mentioned in our last issue, was grown in a comparatively new fruit region—north-western Arkansas—but which has fairly earned its new title of "The Orchard of America." Through the courtesy of Mr. D. Wischart, general passenger agent of the St. Louis and San Francisco railway, a representative of the *Farmers' Review* enjoyed a most delightful trip through this garden of Eden. The St. Louis and San Francisco railroad passes through some of the richest and finest farming lands of south western Missouri, and then across the great fruit-bearing belt of north-western Arkansas. If there are any particular sections which are favored more than others, we could not hesitate in selecting the counties of Washington and Benton as the cream of all the land traversed by the St. Louis and San Francisco railway. At the Fort Smith fair the display of fruit and other farm products from the above-named counties was exceedingly grand, and, as was to be expected, the exhibitors from that favored section of the State carried off the honors over the heads of most worthy competitors from other parts of the country. Crawford, Washington and Benton counties lie adjacent to the famous Cherokee lands in the Indian Territory, each being cut in half by the St. Louis and San Francisco railway, which has its mid-continent depot at Fort Smith on the Arkansas river. The soil is as rich as the Oklahoma lands, the climate all that could be desired—never too hot and never so cold as to injure any kind of fruit trees. The people are sociable, cultivated and full of enterprise, rich in their possessions and content with the beauty of their surroundings. The Chicagoan, who visits north-western Arkansas for the first time, is disappointed in not meeting with cow-boys and other unsavory denominations which figure chiefly in yellow-back literature and sensational sporting sheets. On the contrary he finds an industrious and intelligent people, happy in their increasing wealth; school houses and churches are nearly as numerous as in the longer settled states of Indiana, Ohio and Illinois. Aside from the fertility of the soil, climate, and other natural advantages, this country owes its rapid advancement and development to the St. Louis and San Francisco railway which provides rapid transportation of the crops to the markets of St. Louis and Chicago. Persons seeking new homes in the West should visit the north-western portion of Arkansas before making a selection of land, and when they do they will thank the *Farmers' Review* for calling their attention to this—a new Eldorado.—*Farmers' Review*.

BURMESE PETROLEUM.

[COMMUNICATED]

CONSIDERING the intense and universal interest now centred on Burmah, with the probability of annexation, and almost certainty of British supervision; it is to be hoped that her resources of wealth in petroleum will no longer be neglected as hitherto. It is beyond question a grave scandal, that throughout the Indian empire, we should be using kerosine from America, for no better reason than a sort of oriental apathy that prevents us, up to date, from using some of the enormous supplies so close at hand. We shall do well to ponder over the very opposite qualifications; that is to say, the indomitable energy and perseverance of Messrs. Nobel at Baku on the Caspian Sea. Messrs Nobel have received no assistance from any one. They wanted means of carriage—receiving no help, they constructed their own fleet of steamers, and constructed them to use their own petroleum waste as fuel; they then wanted larger ones to take the petroleum to a railway station on the Volga; they constructed the larger, they asked the railway for oil trucks; the railway authorities made none, so Messrs Nobel made their own trucks; though of course the railways profited equally by the traffic. Then as ice blocked the river for long periods, they wanted a large number of spacious depôts. Again Messrs Nobel were not to be beaten, and made the depôts for themselves, feeling the railway authorities to conduct the sales, and great has been the reward for all this energy. Locomotives using this fuel are running day by day nearer to our northern boundaries, and the latest news is, that Messrs Nobel's kerosine is entering the Bombay and Kurrachee markets, to compete with the American article, as it has already so successfully done in Russia—and we, what have we done? We have found the oil near Meiktila, and we have known of it for many years near Rangoon; but there the story ends. In these days of experiments all forms of work, as heat units, it is not difficult to perceive what enormous resources the presence of petroleum lays bare. Not only shall we have exceedingly cheap fuel all over India, we shall also, in many cases, solve the difficult question of preserving our hills from being denuded of fuel and interfering with our rainfall, but we shall also gradually introduce the singular and cheap forms of engines used for so many purposes near Baku. We shall have a fleet of oil-burning

steamers on the Irrawaddy first, and later on to England itself. Practical men will soon realize the convenience of a run to England and back, without losing time to coal even once on the journey. All who have tried it say there is nothing so satisfactory as the automatic stoker who never neglects his work, i.e., the self-feeding engine. But these results, and many more, of which we have no space to speak at present, are not to be obtained by sitting still with folded hands. Unless we wish such a man as Robert Nobel to step in and take the trade from us, we must bestir ourselves, learn a lesson from Messrs Nobel or brother Jonathan, and lose no time in starting business. We have no hesitation in saying that this is the most important thing to be done in Burmah. All other trades will follow in its wake, for it will afford means of communication by land and sea.—*Madras Mail*.

HYDROCHLORATE OF COCAINE.

DR. FREUD, of Vienna, published in August a research on the alkaloid, which stated that it caused local anaesthesia of the tongue. Dr. Koller argued that if it deadened the sensibility of the nerves of the tongue, it would have a similar effect on the nerves of the eye. After many experiments on animals, on himself and friends, and afterwards on patients, he published his discovery at the Heidelberg Ophthalmological Congress in September.

We will give a short account of the results that seem to have been obtained in various departments:—

The Eye.—One or two drops of a 4 per cent solution instilled into the eye cause at first a stinging sensation lasting a few seconds. On repeating the application there is a sensation of cold, then comes a feeling of weight or tension and dryness. The eye protrudes somewhat. If the instillation is repeated the pupil dilates. Five minutes after the first instillation the cornea can be handled quite roughly, cut, cauterised with silver nitrate, pitted by pressure, without causing the slightest pain or even sensation. There is simply no feeling. When deep incisions are made as for iridectomy pain has been observed by some, though not by others. It is as yet doubtful how deeply the anaesthetic effect can be made to extend; it passes off at the surface in about twenty minutes, and as it apparently takes time to reach the lower structures shown by the dilation of the pupil, it would seem that the application must be repeated to obtain the best effect. The eye remains dilated for some time, but vision is not interfered with, and the eye gradually returns to its normal state. We find reports of three cases where inflammation has occurred after the use of the drug among a very large number, in which it was not observed. One patient who had undergone two iridectomies under others had the globe of the eye excised by Mr. Carmalt Jones under the influence of a 2 per cent solution of cocaine. His remark was that it was a great deal better than that beastly ether.

Eyelid.—Mr. Bader has crushed a tumour on the eyelid without causing pain to the patient.

The Tongue.—Mr. T. Smith applied a 20 per cent solution to the tongue of a patient three times within ten minutes. He then applied fuming nitric acid freely two or three times so as to produce a definite burn. No pain was felt during the operation.

The Nose.—H. J. Butlin records his own experience. He has twice had the turbinated bones of his nose burned by Dr. Semon at intervals of three weeks. The first operation caused intense pain and prostration. At the second, the surface of the bones was painted thoroughly twice over with an interval of five minutes, with a twenty per cent solution of the hydrochlorate. The effect was marvellous, far more so than I or even he, I think, expected. The burning was not felt by me more than the introduction of the brush in painting. I cannot say I did not feel the operation, but the sensation must be described as feeling no pain.

The Larynx.—Dr. Semon has also removed growths from the larynx of a lady in whom, at the seven previous operations, the mere introduction of the instrument had caused alarming shocks. After painting the interior of larynx with the 20 per cent solution once, and waiting five minutes, he was able to introduce the instrument four times, and remove considerable portions of the growth, without the patient experiencing any pain at the moment, or subsequent shock hypodermically.

Messrs. J. H. E. Brock and C. J. Arkie, of University College Hospital, have tried the effect of hypodermic injections. The effects, which were common to all the injections were smarting followed by numbness, redness round the point of injection; in fact, in two to three minutes, sensation to touch was diminished, to pain and temperature completely abolished. In every experiment except the last when half-grain was injected into the forearm, the anaesthetic area was more extensive immediately above the point of injection than below. The extent of surface on which the above effects were produced was about half an inch above and a quarter of an inch below the point of injection; while for about half an inch around this area there was a slight diminution to tactile, painful, and thermal impression. They have performed two minor surgical operations painlessly after an injection of one-seventh of a grain.

We have given only some of the more striking pieces of evidence that have been brought forward.—*Chemist and Druggist*.

CHEESE-MAKING.

RENNET AND SALT.

The following address was delivered by J. B. Harris, Canadian Cheese Instructor in Galloway and Dumfriesshire, at the meeting of the Scottish Dairy Association in Kilmarnock on Wednesday week :-

Rennet is the second agent applied in cheese-making, heat being the first. It does not seem to be thoroughly understood by cheese-makers, as they use the same quantity in spring, summer, and autumn, regardless of the quality of the milk, or time of curing their product. I might write a treatise on rennet, but we will take it for granted that all know how to prepare it. In this short paper I will only touch on its use. I was requested by your secretary to read a short paper on some subject of my own choosing, and knowing that rennet and salt were the shoals that wrecked most cheese-makers, I thought it best to give a few hints on these important agents. I have made remarks over and over on the importance of proper treatment with rennet and salt.

Rennet seems to be the only sure agent by which the cheesy matter of milk can be separated from the whey. Nature seems to have provided it for the cheese-makers' especial use. Its office is not simply to produce coagulation; it goes further, and exercises an important part not only in the curing of the cheese, but also in bringing about that condition which we call digestibility. No other substance of which we have any knowledge is capable of bringing about the same result. In view of these facts more than one idea should govern us in the use of the rennet. If it is intended that the cheese shall go into market in from forty to fifty days (which should always be the case in the early part of the season with fodder-made cheese), enough of rennet should be used to ensure the process of coagulation, beginning in from 10 to 12 minutes, with milk in proper condition. Rennet sufficient to accomplish this result will, in the time limited for sale, have performed all that is desired in preparing the product for the table. It will be seen by this, if we have been clear in explaining the idea, that the time of curing rather than the condition and quality of milk should govern the quantity used. Milk well matured will coagulate with less rennet than when sweet and new, but this should make no difference with the quantity used, as the curing of the cheese is what we must consider. If the milk is partly skimmed, or in a time of year that it is not so rich, more rennet should be used, as the richer the milk, the less rennet is required. This is where many cheese makers fail, who never change their quantity in spring, summer, or autumn. I found many dairies the past season in which splendid cheese was made through June, July, and part August; but when milk became richer, by reason of the cows giving a less quantity, their cheese was soft. If they had decreased their rennet, and increased their heat and salt, their product would have been firm, solid, and good in texture.

The office of rennet cannot be explained more definitely than by saying that when it is mingled with milk it solidifies the caseine or albuminous portion of that fluid. This solidification is called coagulation. In the coagulation of milk the cream is held in suspension and the whey expelled. The function of rennet in curing is much the same as that of the gastric juice of the stomach, breaking down as it does the fibre of the curd, and carrying it towards a condition like that of chyle in the digestive process.

There are no rules by which we may be governed in the use of salt other than very general ones. We should bear in mind always that a portion passes off in the whey in pressing, more or less according to the amount of moisture contained in the curd. We should remember that the purpose of salt is not simply to secure flavour; it is used also as a preservative, and a check upon the action of rennet. We must therefore have in mind four distinct considerations in the application of salt. First, the amount of loss to be sustained in pressing; second, flavour; third, the amount of rennet used; and fourth, the time of curing. By the use of salt we so balance a set of natural processes as to compel them in a given length of time to produce for us a given result—it depending altogether on the skill of the operator what that result shall be.

From what has been said it will appear that little, if anything, can be effected by the use of figures in regard to the quantity of salt to be used. However, we will give two general propositions which may serve in some degree as a guide to the operator in this matter.

When curd contains about 40 per cent of moisture it is in its normal condition, and when this is the case and we desire to sell in 40 or 50 days, we should use $1\frac{1}{2}$ lbs. to each 100 lbs. of curd. Again, with the curd normal in moisture, if we desire that our product remain on ourselves indefinitely, we should use $2\frac{1}{2}$ lbs.

From this it will be seen that in the use of the salt we should take into consideration not only the condition of the curd as to moisture, but also the time that is required for curing, thus avoiding the error of using a quantity of salt which would counteract or limit the action of the rennet, as it is a well-known fact that salt and rennet work in opposite directions.—N. B. Agriculturist.

TEA AND HOW TO MAKE IT.

The following letter, dated 14th March 1885, was addressed by R. Z. Darrah, Esq., officiating Director of Agriculture, Assam, to G. M. Barton, Esq., Secretary, Indian Tea Association, and will doubtless be read with interest by lovers of tea :-

About the middle of last month I visited the Bhutia encampment of Dewangiri, and among other matters, I enquired into the subject of tea. I found that the Bhutias had as usual brought with them a few bricks of the commodity they designate tea. I obtained a small quantity, and noted a few particulars, which may possibly prove of interest.

2. The Bhutias stated that the tea was brought by traders from a place called Janajippoo, situated a year's journey to the north-east. To indicate the direction, they pointed at first due north, and then due east, intimating that a traveller to Janajippoo from Bhutan would have first to go north and then east. They stated that they had given in exchange for a brick two cloths of eri-silk, each cloth containing as much thread as they had bought for the equivalent of Rs. 1-4 in the Assam Valley. Estimating roughly the labour of weaving at 12 annas per cloth, the cost of the tea would appear to have been Rs. 4 per brick. That this could not be its real price in Bhutan was proved by the fact that I bought it at Rs. 3-8 in Dewangiri. The price last year was as far as I can ascertain Rs. 2-4 in the same place. The Bhutias stated that it had become dearer in the interior. I enquired why they drank tea which had come such a distance, when a much cheaper kind was to be obtained in Assam. They stated that Assam tea was bitter, but the tea they had with them was sweet.

3. I watched in one instance the process of making the infusion: The pots, one of brass and filled with water, the other an earthen one and empty, were put over a fire; a piece was broken off a brick of tea and crumbled up in the hand to separate the adhering leaves and twigs. The handful so obtained was put into the dry earthen pot and stirred up for a few seconds till hot. Then, about a couple of wine glasses of potash water (made by straining water through ash) poured on the dry tea, and when the heat had almost evaporated, another spoonful of water (now hot) was added to the brass pot. The tea meanwhile was kept stirred to prevent burning, and when nearly dry, a second, and then a third, spoonful of water was added; when this, almost dry, all the water from the brass pot was poured a teaspoonful of salt having been put in, the mixture was As soon as the bubbles showed that the liquid was boiling, ladled out with a spoon formed from a gourd into a churn made from a thick piece of bamboo about two feet long. The churn was provided with a wooden cover, through a hole in which a piston-rod worked, the piston being simply a round piece of wood, roughly fitting the interior of the churn. The boiling liquid having been poured in, the churn was worked for a few seconds, and then about a tablespoonful of ghee was added to the mixture. The churn up to this was worked vigorously for a few minutes, considerable pressure being evidently required to force the piston up and down. The Bhutia next poured back the liquid into the earthen pot (which meanwhile had remained on the fire) and tasted the tea. He stated that more salt was wanted, and accordingly about an eggspoonful. The whole was boiled again, about a minute, and then tasted and pronounced excellent. The amount was about equal to the contents of two ordinary quart bottles.

4. Attempts have, I believe, been made to produce from the refuse of tea gardens a substance resembling Bhutia brick tea, but so far, I believe, they have been unsuccessful. It would seem, however, that the endeaour should not be given up as there can be little doubt that if planters could manufacture a commodity which would not the taste of the Bhutias, Assam tea might penetrate eventually in Central Asia. Bhutia tea can hardly be the produce of any country but China, and although recent enquiries tend to show that China tea can be carried without much cost into Tibet, yet it is hardly possible that Assam tea can not undersell it. Even supposing that the Bhutias are not doubting the real price to their statement to me, and that Chinese tea can be bought at Rs. 1-8 per brick (about 50 lbs. per lb.), I imagine an Assam planter, who could produce similar article at all, could do so for 3 annas per lb. at a price which would certainly enable him to sell with a profit, and at a price which would probably induce the Bhutias to buy.

5. The obvious objection to any attempt to manufacture brick tea is that, even if made, trade with the tribes on the Assam border is too inconsiderable to produce a sound as far as industry of Assam. The objection is perfectly sound as far as these tribes are themselves concerned, but the Bhutias perceive that they can buy the materials for an extraordinary mixture they call tea at a cheaper rate in Assam than in Bhutan itself, they are certain to make their purchases there instead of in the interior. Once introduced at a cheap rate into Bhutan, it is more than probable that our tea would find its way into Tibet, and its spread in the interior of Central Asia, could be then regulated mainly by the cost of its carriage from China, as compared with the cost of carriage of Chinese tea.

6. The above considerations had led me to obtain samples of the stuff the Bhutias use, and I am sending you a small box containing three bricks of tea and two sealed bottles of the infusion I saw made. You will be the best judge of the method in which the samples should be considered, and your taking action, subject sufficiently.

BOGUS BUTTER.

We are in receipt of a little publication by Prof. Lorenz Pagsten on the art of testing and detecting adulteration between genuine and bogus butter, by an apparatus of his invention. It has numerous illustrations showing the appearance under the microscope of the living germs found in such mixtures, which we are unable to produce. The following, however, taken from the treatise will be of interest. We only wish that the illustrations with the illustrations could have a wider circulation among the butter consumers of the country.

WHAT IS BOGUS BUTTER?

1. Bogus butter is raw lard or raw tallow deprived of its offensive smell by means of acids or alkalies, and generally coloured with milk in order to acquire by chemical decomposition a bogus flavour.

Explanation of process:

"The sugar of milk is split up into lactic acid, and part of the lactic acid is converted into butyric acid (bogus flavour). The process is accompanied by putrid fermentation, and the development of myriads of microscopic infusoria or organisms of vegetable and animal origin" closely allied to the germs supposed to be the cause of infectious diseases.

Living organisms.

These are classed as follows: First—Yeast fermentation. Second—Acid fermentation. Third—Putrid fermentation.

"These organisms move forward by sliding. Their body remains rigid or undulates slightly; they balance themselves on end and agitate their extremities, they are often bent."

"These singular organisms are reproduced by fission."

4. When deodorization is accomplished by alkalies, the lye used gelatinizes the animal membranes and skins surrounding the lard or tallow into a glue. Soap is formed. White specks of alkali and protein compounds adhere to the sides, and a coarse alkaline film sinks to the bottom of the tub.

Then the object of the butter mixer has been obtained, the action of the originally transparent lard or tallow is manifested by the lumpy and turbid opaqueness of the product. The fine raw lard or raw tallow is deodorized by mineral incrementation takes place.

5. A part of the hydrogen of the fat is displaced by nitro oxide or sulphur of the acids, and, under favorable conditions, fat is deprived of part of its carbon, which unites with the nitro oxide to form oxalic acid.

6. The result is, in the main, the same as mentioned in No. 4. The butter now assumes a reddish tint; skins and membranes are broken up into small pieces, and the mixture is always strongly acid.

7. Lard or raw tallow cannot be churned or mixed with genuine butter without the changes taking place mentioned in No. 2, as a temperature from 80 to 100 degrees would have to be maintained for a sufficient time to mature the mixture.

8. Bogus butter when made has reached the limit of its acidity, any further change in the composition is to putrefaction.

9. Genuine butter is a mixture of neutral fats—glycerides—which may be divided into two main classes.

Class 1—High in carbon, melts at a high temperature, and is volatile. Fat becomes transparent at 150 degrees or over (all butter).

Sub class 2—Low in carbon, melts at a low temperature, volatile and fragrant. Fat becomes transparent between 95 and 105 degrees (Genuine butter). No free fatty acids being present.

10. Grass butter is rich in fats of sub class 2, and will not keep so well as fat butter, which consists mainly of fats of sub class 1.

11. Bogus butter is a corruption of raw lard or raw tallow in the form of chlorine, sulphur, or nitro derivatives, mixed with free acids and mineral acids, animal skins—sometimes gelatinized—and undergoing the process of lactic, butyric, and putrid fermentation.

12. Any temperature below 212 degrees is dangerous to the health of the consumer.

13. The acid causes irritation of the bowels and is productive of colic and pain.

14. Oxalic acid is a powerful and rapidity of its action has caused it to be used for medicinal purposes.

15. The effects of the acid, bacteria and influenza in general are too well known to require any repetition, and the possibility of the presence of the acid and tape worm eggs is equally well established.

16. Mineral acids, such as glue, stearic acid, soap, and skins cannot properly be classed as adulterants.

17. Any chemical analysis of fats is incomplete unless qualified by optical and microscopic examinations.

18. Farmers' Review.

HOLLOWAY'S OINTMENT AND PILLS—Autumnal Remedies.—Towards the fall of the year countenance great work to lower the tone of the nervous system, which is followed by ill health unless proper means be employed to ward off that evil. Holloway's (as named preparations) apply a full remedy for both external and internal complaints connected with the organs of season. All affections of the skin, eruptions, pimples, superficial and deeper seated inflammations, or violent rheumatic pains, and gummy humors alike succumb to the healing power of Holloway's Ointment and Pills, which will effect a permanent cure in the most obstinate cases, though the symptoms of the disease are legion, and have obstinately withstood the best medical aid.

A BENEFICIAL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising and lying down a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels constive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often times there is a palpitation of the heart, and the patient fears he may have heart disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon Road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARY STREET, PERERBOURGH.

November 29th, 1885.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia, but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr A. J. WHITE.

WILLIAM BRENT

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. One customer described it as a "cure for dyspepsia," and always recommends it with confidence. Faithfully yours,

(Sd.) VINCENT A. WILLIAMS.

To Mr A. J. WHITE.

Chemist Dentist, Mothyr Lydvil.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constipation.

Preston, Sept 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

To A. J. WHITE, Esq.

(Signed) W. BOWMAN.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint, with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (having continued taking it), I am glad to say that I am a different being altogether. It is said of certain poets that they "come as a balm and a blessing to men," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "balm and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Grateful for the benefit I have derived from the excellent preparation, I beg to inform you with this unqualified testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CHAS. B. BERRY,

A. J. WHITE, Esq.

Baptist Missionary.

King's College, Whitehaven, October 18, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. It has now been so long that it has restored me to complete health.—I remain, Sir, your obedient servant.

(Sd.)

(Signed) JOHN D. LIGHTFOOT.
